INTRODUCTION

BayesPy provides tools for Bayesian inference with Python. The user constructs a model as a Bayesian network, observes data and runs posterior inference. The goal is to provide a tool which is efficient, flexible and extendable enough for expert use but also accessible for more casual users.

Currently, only variational Bayesian inference for conjugate-exponential family (variational message passing) has been implemented. Future work includes variational approximations for other types of distributions and possibly other approximate inference methods such as expectation propagation, Laplace approximations, Markov chain Monte Carlo (MCMC) and other methods. Contributions are welcome.

It is recommended to use the latest version from the GitHub master branch. The version in PyPI is quite outdated.

1.2 Similar projects

VIBES (http://vibes.sourceforge.net/) allows variational inference to be performed automatically on a Bayesian network. It is implemented in Java and released under revised BSD license.

Bayes Blocks (http://research.ics.aalto.fi/bayes/software/) is a C++/Python implementation of the variational building block framework. The framework allows easy learning of a wide variety of models using variational Bayesian learning. It is available as free software under the GNU General Public License.

Infer.NET (http://research.microsoft.com/infernet/) is a .NET framework for machine learning. It provides message-passing algorithms and statistical routines for performing Bayesian inference. It is partly closed source and licensed for non-commercial use only.

PyMC (https://github.com/pymc-devs/pymc) provides MCMC methods in Python. It is released under the Academic Free License.

OpenBUGS (http://www.openbugs.info) is a software package for performing Bayesian inference using Gibbs sampling. It is released under the GNU General Public License.

Dimple (http://dimple.probprog.org/) provides Gibbs sampling, belief propagation and a few other inference algorithms for Matlab and Java. It is released under the Apache License.

Stan (http://mc-stan.org/) provides inference using MCMC with an interface for R and Python. It is released under the New BSD License.

PBNT - Python Bayesian Network Toolbox (http://pbnt.berlios.de/) is Bayesian network library in Python supporting static networks with discrete variables. There was no information about the license.

CHAPTER

TWO

USER GUIDE

2.1 Installation

BayesPy is a Python 3 package and it can be installed from PyPI or the latest development version from GitHub. The instructions below explain how to set up the system by installing required packages, how to install BayesPy and how to compile this documentation yourself. However, if these instructions contain errors or some relevant details are missing, please file a bug report at https://github.com/bayespy/bayespy/issues.

2.1.1 Installing requirements

BayesPy requires Python 3.2 (or later) and the following packages:

- NumPy (>=1.8.0),
- SciPy (>=0.13.0)
- matplotlib (>=1.2)
- h5py

Ideally, a manual installation of these dependencies is not required and you can skip to the next section "Installing Bayespy". However, there are several reasons why the installation of BayesPy as described in the next section won't work because of your system. Thus, this section tries to give as detailed and robust a method of setting up your system such that the installation of BayesPy should work.

A proper installation of the dependencies for Python 3 can be a bit tricky and you may refer to http://www.scipy.org/install.html for more detailed instructions about the SciPy stack. If your system has an older version of any of the packages (NumPy, SciPy or matplotlib) or it does not provide the packages for Python 3, you may set up a virtual environment and install the latest versions there. To create and activate a new virtual environment, run

```
virtualenv -p python3 --system-site-packages ENV
source ENV/bin/activate
```

If you have relevant system libraries installed (C compiler, Python development files, BLAS/LAPACK etc.), you may be able to install the Python packages from PyPI. For instance, on Ubuntu (>= 12.10), you may install the required system libraries for each package as:

```
sudo apt-get build-dep python3-numpy
sudo apt-get build-dep python3-scipy
sudo apt-get build-dep python3-matplotlib
sudo apt-get build-dep python-h5py
```

Then installation/upgrade from PyPI should work:

```
pip install distribute --upgrade
pip install numpy --upgrade
pip install scipy --upgrade
pip install matplotlib --upgrade
pip install h5py
```

Note that Matplotlib requires a quite recent version of Distribute (>=0.6.28). If you have problems installing any of these packages, refer to the manual of that package.

2.1.2 Installing BayesPy

If the system has been properly set up and the virtual environment is activated (optional), latest release of BayesPy can be installed from PyPI simply as

```
pip install bayespy
```

If you want to install the latest development version of BayesPy, use GitHub instead:

```
pip install https://github.com/bayespy/bayespy/archive/master.zip
```

It is recommended to run the unit tests in order to check that BayesPy is working properly. Thus, install Nose and run the unit tests:

```
pip install nose
nosetests bayespy
```

2.1.3 Compiling documentation

This documentation can be found at http://bayespy.org/. The documentation source files are readable as such in reStructuredText format in doc/source/ directory. It is possible to compile the documentation into HTML or PDF yourself. In order to compile the documentation, Sphinx is required and a few extensions for it. Those can be installed as:

```
pip install sphinx sphinxcontrib-tikz sphinxcontrib-bayesnet
```

In addition, the numpydoc extension for Sphinx is required. However, the latest stable release (0.4) does not support Python 3, thus one needs to install the development version:

```
pip install https://github.com/numpy/numpydoc/archive/master.zip
```

In order to visualize graphical models in HTML, you need to have pnmcrop. On Ubuntu, it can be installed as

```
sudo apt-get install netpbm
```

The documentation can be compiled to HTML and PDF by running the following commands in the doc directory:

```
make html
make latexpdf
```

2.1.4 Converting notebooks

The documentation uses IPython notebooks for the examples. This is a convenient format for sharing Python examples with comments. The notebooks can be converted, for instance, to documentation files or Python scripts. BayesPy repository contains those notebook files (.ipynb) and their conversions to RST format for the documentation. If you

want to convert the notebooks into RST files, Python scripts or some other format yourself, follow these instructions. First, the following packages are required:

```
pip install ipython pyzmq
```

You need quite a recent IPython. You may also need to install Pandoc. In Ubuntu, this can be done as:

```
sudo aptitude install pandoc
```

Now, the notebooks can be converted to RST for the documentation by running the following command in the doc directory:

```
make notebooks
```

Or you can convert the notebooks to RST or Python (or something else) for your own use:

```
ipython nbconvert --to rst doc/source/_notebooks/*.ipynb
ipython nbconvert --to python doc/source/_notebooks/*.ipynb
```

The Python scripts can be used to run the examples as such. There are also more formats available in case you want the examples in HTML, LaTeX, or some other format.

You can also open the notebooks interactively in a web browser by going to the notebooks directory and running the IPython notebook:

```
cd doc/source/_notebooks
ipython notebook
```

This should run a simple server and open a web browser.

You can also run doctest to test code snippets in the documentation:

```
make doctest
```

or in the docstrings:

```
nosetests --with-doctest bayespy
```

2.2 Quick start guide

This short guide shows the key steps in using BayesPy for variational Bayesian inference by applying BayesPy to a simple problem. The key steps in using BayesPy are the following:

- · Construct the model
- Observe some of the variables by providing the data in a proper format
- Run variational Bayesian inference
- Examine the resulting posterior approximation

To demonstrate BayesPy, we'll consider a very simple problem: we have a set of observations from a Gaussian distribution with unknown mean and variance, and we want to learn these parameters. In this case, we do not use any real-world data but generate some artificial data. The dataset consists of ten samples from a Gaussian distribution with mean 5 and standard deviation 10. This dataset can be generated with NumPy as follows:

```
>>> import numpy as np
>>> data = np.random.normal(5, 10, size=(10,))
```

2.2.1 Constructing the model

Now, given this data we would like to estimate the mean and the standard deviation as if we didn't know their values. The model can be defined as follows:

$$p(\mathbf{y}|\mu,\tau) = \prod_{n=0}^{9} \mathcal{N}(y_n|\mu,\tau)$$
$$p(\mu) = \mathcal{N}(\mu|0, 10^{-6})$$
$$p(\tau) = \mathcal{G}(\tau|10^{-6}, 10^{-6})$$

where \mathcal{N} is the Gaussian distribution parameterized by its mean and precision (i.e., inverse variance), and \mathcal{G} is the gamma distribution parameterized by its shape and rate parameters. Note that we have given quite uninformative priors for the variables μ and τ . This simple model can also be shown as a directed factor graph: This model can be

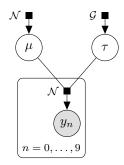

Figure 2.1: Directed factor graph of the example model.

constructed in BayesPy as follows:

```
>>> from bayespy.nodes import GaussianARD, Gamma
>>> mu = GaussianARD(0, 1e-6)
>>> tau = Gamma(1e-6, 1e-6)
>>> y = GaussianARD(mu, tau, plates=(10,))
```

This is quite self-explanatory given the model definitions above. We have used two types of nodes GaussianARD and Gamma to represent Gaussian and gamma distributions, respectively. There are much more distributions in bayespy.nodes so you can construct quite complex conjugate exponential family models. The node y uses keyword argument plates to define the plates $n=0,\ldots,9$.

2.2.2 Performing inference

Now that we have created the model, we can provide our data by setting y as observed:

```
>>> y.observe(data)
```

Next we want to estimate the posterior distribution. In principle, we could use different inference engines (e.g., MCMC or EP) but currently only variational Bayesian (VB) engine is implemented. The engine is initialized by giving all the nodes of the model:

```
>>> from bayespy.inference import VB
>>> Q = VB(mu, tau, y)
```

The inference algorithm can be run as long as wanted (max. 20 iterations in this case):

```
>>> Q.update(repeat=20)

Iteration 1: loglike=-6.020956e+01 (... seconds)

Iteration 2: loglike=-5.820527e+01 (... seconds)

Iteration 3: loglike=-5.820290e+01 (... seconds)

Iteration 4: loglike=-5.820288e+01 (... seconds)

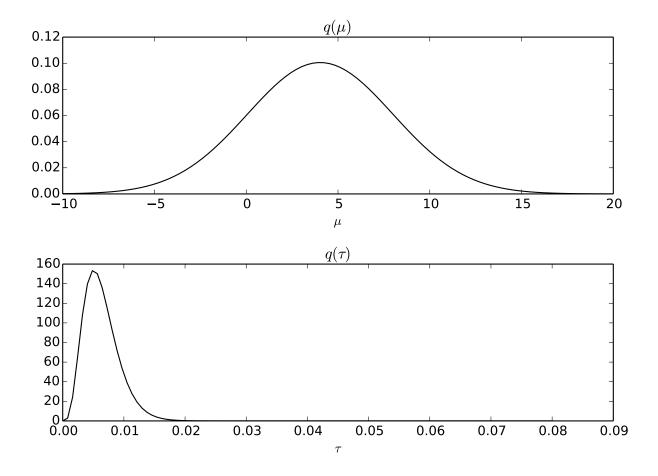

Converged at iteration 4.
```

Now the algorithm converged after four iterations, before the requested 20 iterations. VB approximates the true posterior $p(\mu, \tau | \mathbf{y})$ with a distribution which factorizes with respect to the nodes: $q(\mu)q(\tau)$.

2.2.3 Examining posterior approximation

The resulting approximate posterior distributions $q(\mu)$ and $q(\tau)$ can be examined, for instance, by plotting the marginal probability density functions:

```
>>> import bayespy.plot as bpplt
>>> bpplt.pyplot.subplot(2, 1, 1)
<matplotlib.axes.AxesSubplot object at 0x...>
>>> bpplt.pdf(mu, np.linspace(-10, 20, num=100), color='k', name=r'\mu')
[<matplotlib.lines.Line2D object at 0x...>]
>>> bpplt.pyplot.subplot(2, 1, 2)
<matplotlib.axes.AxesSubplot object at 0x...>
>>> bpplt.pdf(tau, np.linspace(1e-6, 0.08, num=100), color='k', name=r'\tau')
[<matplotlib.lines.Line2D object at 0x...>]
>>> bpplt.pyplot.tight_layout()
>>> bpplt.pyplot.show()
```

This example was a very simple introduction to using BayesPy. The model can be much more complex and each phase contains more options to give the user more control over the inference. The following sections give more details about the phases.

2.3 Constructing the model

In BayesPy, the model is constructed by creating nodes which form a directed network. There are two types of nodes: stochastic and deterministic. A stochastic node corresponds to a random variable (or a set of random variables) from a specific probability distribution. A deterministic node corresponds to a deterministic function of its parents. For a list of built-in nodes, see the *User API*.

2.3.1 Creating nodes

Creating a node is basically like writing the conditional prior distribution of the variable in Python. The node is constructed by giving the parent nodes, that is, the conditioning variables as arguments. The number of parents and their meaning depend on the node. For instance, a Gaussian node is created by giving the mean vector and the precision matrix. These parents can be constant numerical arrays if they are known:

```
>>> from bayespy.nodes import Gaussian
>>> X = Gaussian([2, 5], [[1.0, 0.3], [0.3, 1.0]])
```

or other nodes if they are unknown and given prior distributions:

```
>>> from bayespy.nodes import Gaussian, Wishart
>>> mu = Gaussian([0, 0], [[1e-6, 0], [0, 1e-6]])
>>> Lambda = Wishart(2, [[1, 0], [0, 1]])
>>> X = Gaussian(mu, Lambda)
```

Nodes can also be named by providing name keyword argument:

```
>>> X = Gaussian(mu, Lambda, name='x')
```

The name may be useful when referring to the node using an inference engine.

For the parent nodes, there are two main restrictions: non-constant parent nodes must be conjugate and the parent nodes must be mutually independent in the posterior approximation.

Conjugacy of the parents

In Bayesian framework in general, one can give quite arbitrary probability distributions for variables. However, one often uses distributions that are easy to handle in practice. Quite often this means that the parents are given conjugate priors. This is also one of the limitations in BayesPy: only conjugate family prior distributions are accepted currently. Thus, although in principle one could give, for instance, gamma prior for the mean parameter mu, only Gaussian-family distributions are accepted because of the conjugacy. If the parent is not of a proper type, an error is raised. This conjugacy is checked automatically by BayesPy and NoConverterError is raised if a parent cannot be interpreted as being from a conjugate distribution.

Independence of the parents

Another a bit rarely encountered limitation is that the parents must be mutually independent (in the posterior factorization). Thus, a node cannot have the same stochastic node as several parents without intermediate stochastic nodes. For instance, the following leads to an error:

```
>>> from bayespy.nodes import Dot
>>> Y = Dot(X, X)
Traceback (most recent call last):
...
ValueError: Parent nodes are not independent
```

The error is raised because X is given as two parents for Y, and obviously X is not independent of X in the posterior approximation. Even if X is not given several times directly but there are some intermediate deterministic nodes, an error is raised because the deterministic nodes depend on their parents and thus the parents of Y would not be independent. However, it is valid that a node is a parent of another node via several paths if all the paths or all except one path has intermediate stochastic nodes. This is valid because the intermediate stochastic nodes have independent posterior approximations. Thus, for instance, the following construction does not raise errors:

```
>>> from bayespy.nodes import Dot
>>> Z = Gaussian(X, [[1,0], [0,1]])
>>> Y = Dot(X, Z)
```

This works because there is now an intermediate stochastic node Z on the other path from X node to Y node.

2.3.2 Effects of the nodes on inference

When constructing the network with nodes, the stochastic nodes actually define three important aspects:

- 1. the prior probability distribution for the variables,
- 2. the factorization of the posterior approximation,

3. the functional form of the posterior approximation for the variables.

Prior probability distribution

First, the most intuitive feature of the nodes is that they define the prior distribution. In the previous example, mu was a stochastic GaussianARD node corresponding to μ from the normal distribution, tau was a stochastic Gamma node corresponding to τ from the gamma distribution, and y was a stochastic GaussianARD node corresponding to y from the normal distribution with mean μ and precision τ . If we denote the set of all stochastic nodes by Ω , and by π_X the set of parents of a node X, the model is defined as

$$p(\Omega) = \prod_{X \in \Omega} p(X|\pi_X),$$

where nodes correspond to the terms $p(X|\pi_X)$.

Posterior factorization

Second, the nodes define the structure of the posterior approximation. The variational Bayesian approximation factorizes with respect to nodes, that is, each node corresponds to an independent probability distribution in the posterior approximation. In the previous example, mu and tau were separate nodes, thus the posterior approximation factorizes with respect to them: $q(\mu)q(\tau)$. Thus, the posterior approximation can be written as:

$$p(\tilde{\Omega}|\hat{\Omega}) \approx \prod_{X \in \tilde{\Omega}} q(X),$$

where $\tilde{\Omega}$ is the set of latent stochastic nodes and $\hat{\Omega}$ is the set of observed stochastic nodes. Sometimes one may want to avoid the factorization between some variables. For this purpose, there are some nodes which model several variables jointly without factorization. For instance, GaussianGammaISO is a joint node for μ and τ variables from the normal-gamma distribution and the posterior approximation does not factorize between μ and τ , that is, the posterior approximation is $q(\mu, \tau)$.

Functional form of the posterior

Last, the nodes define the functional form of the posterior approximation. Usually, the posterior approximation has the same or similar functional form as the prior. For instance, Gamma uses gamma distribution to also approximate the posterior distribution. Similarly, GaussianARD uses Gaussian distribution for the posterior. However, the posterior approximation of GaussianARD uses a full covariance matrix although the prior assumes a diagonal covariance matrix. Thus, there can be slight differences in the exact functional form of the posterior approximation but the rule of thumb is that the functional form of the posterior approximation is the same as or more general than the functional form of the prior.

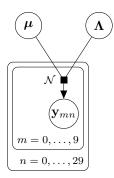

2.3.3 Using plate notation

Defining plates

Stochastic nodes take the optional parameter plates, which can be used to define plates of the variable. A plate defines the number of repetitions of a set of variables. For instance, a set of random variables y_{mn} could be defined as

$$\mathbf{y}_{mn} \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Lambda}), \qquad m = 0, \dots, 9, \quad n = 0, \dots, 29.$$

This can also be visualized as a graphical model:

The variable has two plates: one for the index m and one for the index n. In BayesPy, this random variable can be constructed as:

```
>>> y = Gaussian(mu, Lambda, plates=(10,30))
```

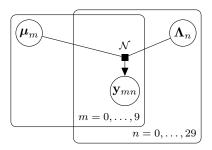

Note: The plates are always given as a tuple of positive integers.

Sharing and broadcasting plates

Instead of having a common mean and precision matrix for all y_{mn} , it is also possible to share plates with parents. For instance, the mean could be different for each index m and the precision for each index n:

$$\mathbf{y}_{mn} \sim \mathcal{N}(\boldsymbol{\mu}_m, \boldsymbol{\Lambda}_n), \qquad m = 0, \dots, 9, \quad n = 0, \dots, 29.$$

which has the following graphical representation:

This can be constructed in BayesPy, for instance, as:

```
>>> from bayespy.nodes import Gaussian, Wishart
>>> mu = Gaussian([0, 0], [[1e-6, 0], [0, 1e-6]], plates=(10,1))
>>> Lambda = Wishart(2, [[1, 0], [0, 1]], plates=(1,30))
>>> X = Gaussian(mu, Lambda)
```

There are a few things to notice here. First, the plates are defined similarly as shapes in NumPy, that is, they use similar broadcasting rules. For instance, the plates (10,1) and (1,30) broadcast to (10,30). In fact, one could use plates (10,1) and (30,) to get the broadcasted plates (10,30) because broadcasting compares the plates from right to left starting from the last axis. Second, X is not given plates keyword argument because the default plates are the plates broadcasted from the parents and that was what we wanted so it was not necessary to provide the keyword argument. If we wanted, for instance, plates (20,10,30) for X, then we would have needed to provide plates=(20,10,30).

The validity of the plates between a child and its parents is checked as follows. The plates are compared plate-wise starting from the last axis and working the way forward. A plate of the child is compatible with a plate of the parent if either of the following conditions is met:

1. The two plates have equal size

2. The parent has size 1 (or no plate)

Table below shows an example of compatible plates for a child node and its two parent nodes:

node	plates							
parent1		3	1	1	1	8	10	
parent2			1	1	5	1	10	
child	5	3	1	7	5	8	10	

Plates in deterministic nodes

Note that plates can be defined explicitly only for stochastic nodes. For deterministic nodes, the plates are defined implicitly by the plate broadcasting rules from the parents. Deterministic nodes do not need more plates than this because there is no randomness. The deterministic node would just have the same value over the extra plates, but it is not necessary to do this explicitly because the child nodes of the deterministic node can utilize broadcasting anyway. Thus, there is no point in having extra plates in deterministic nodes, and for this reason, deterministic nodes do not use plates keyword argument.

Plates in constants

It is useful to understand how the plates and the shape of a random variable are connected. The shape of an array which contains all the plates of a random variable is the concatenation of the plates and the shape of the variable. For instance, consider a 2-dimensional Gaussian variable with plates (3,). If you want the value of the constant mean vector and constant precision matrix to vary between plates, they are given as (3,2)-shape and (3,2,2)-shape arrays, respectively:

```
>>> import numpy as np
>>> mu = [[0,0], [1,1], [2,2]]
>>> Lambda = [ [[1.0, 0.0],
                [0.0, 1.0]],
                [[1.0, 0.9],
. . .
                [0.9, 1.0]],
. . .
                [[1.0, -0.3],
                [-0.3, 1.0]]
>>> X = Gaussian (mu, Lambda)
>>> np.shape(mu)
(3, 2)
>>> np.shape(Lambda)
(3, 2, 2)
>>> X.plates
(3,)
```

Thus, the leading axes of an array are the plate axes and the trailing axes are the random variable axes. In the example above, the mean vector has plates (3,) and shape (2,2), and the precision matrix has plates (3,) and shape (2,2).

Factorization of plates

It is important to undestand the independency structure the plates induce for the model. First, the repetitions defined by a plate are independent a priori given the parents. Second, the repetitions are independent in the posterior approximation, that is, the posterior approximation factorizes with respect to plates. Thus, the plates also have an effect on the independence structure of the posterior approximation, not only prior. If dependencies between a set of variables need to be handled, that set must be handled as a some kind of multi-dimensional variable.

Irregular plates

The handling of plates is not always as simple as described above. There are cases in which the plates of the parents do not map directly to the plates of the child node. The user API should mention such irregularities.

For instance, the parents of a mixture distribution have a plate which contains the different parameters for each cluster, but the variable from the mixture distribution does not have that plate:

```
>>> from bayespy.nodes import Gaussian, Wishart, Categorical, Mixture
>>> mu = Gaussian([[0], [0], [0]], [ [[1]], [[1]], [[1]] ])
>>> Lambda = Wishart(1, [ [[1]], [[1]], [[1]]])
>>> Z = Categorical([1/3, 1/3, 1/3], plates=(100,))
>>> X = Mixture(Z, Gaussian, mu, Lambda)
>>> mu.plates
(3,)
>>> Lambda.plates
(3,)
>>> Z.plates
(100,)
>>> X.plates
(100,)
```

The plates (3,) and (100,) should not broadcast according to the rules mentioned above. However, when validating the plates, Mixture removes the plate which corresponds to the clusters in mu and Lambda. Thus, X has plates which are the result of broadcasting plates () and (100,) which equals (100,).

Also, sometimes the plates of the parents may be mapped to the variable axes. For instance, an automatic relevance determination (ARD) prior for a Gaussian variable is constructed by giving the diagonal elements of the precision matrix (or tensor). The Gaussian variable itself can be a scalar, a vector, a matrix or a tensor. A set of five 4×3 -dimensional Gaussian matrices with ARD prior is constructed as:

```
>>> from bayespy.nodes import GaussianARD, Gamma
>>> tau = Gamma(1, 1, plates=(5,4,3))
>>> X = GaussianARD(0, tau, shape=(4,3))
>>> tau.plates
(5, 4, 3)
>>> X.plates
(5,)
```

Note how the last two plate axes of tau are mapped to the variable axes of tau with shape (4, 3) and the plates of tau are obtained by taking the remaining leading plate axes of tau.

2.3.4 Example model: Principal component analysis

Now, we'll construct a bit more complex model which will be used in the following sections. The model is a probabilistic version of principal component analysis (PCA):

$$\mathbf{Y} = \mathbf{C}\mathbf{X}^T + \text{noise}$$

where \mathbf{Y} is $M \times N$ data matrix, \mathbf{C} is $M \times D$ loading matrix, \mathbf{X} is $N \times D$ state matrix, and noise is isotropic Gaussian. The dimensionality D is usually assumed to be much smaller than M and N.

A probabilistic formulation can be written as:

$$p(\mathbf{Y}) = \prod_{m=0}^{M-1} \prod_{n=0}^{N-1} \mathcal{N}(y_{mn} | \mathbf{c}_m^T \mathbf{x}_n, \tau)$$

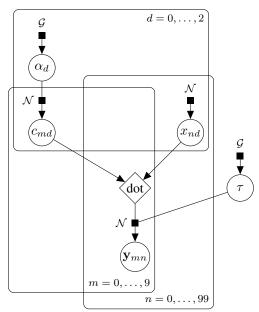

$$p(\mathbf{X}) = \prod_{n=0}^{N-1} \prod_{d=0}^{D-1} \mathcal{N}(x_{nd} | 0, 1)$$

$$p(\mathbf{C}) = \prod_{m=0}^{M-1} \prod_{d=0}^{D-1} \mathcal{N}(c_{md} | 0, \alpha_d)$$

$$p(\boldsymbol{\alpha}) = \prod_{d=0}^{D-1} \mathcal{G}(\alpha_d | 10^{-3}, 10^{-3})$$

$$p(\tau) = \mathcal{G}(\tau | 10^{-3}, 10^{-3})$$

where we have given automatic relevance determination (ARD) prior for C. This can be visualized as a graphical model:

Now, let us construct this model in BayesPy. First, we'll define the dimensionality of the latent space in our model:

```
>>> D = 3
```

Then the prior for the latent states X:

Note that the shape of X is (D,), although the latent dimensions are marked with a plate in the graphical model and they are conditionally independent in the prior. However, we want to (and need to) model the posterior dependency of the latent dimensions, thus we cannot factorize them, which would happen if we used plates=(1,100,D) and shape=(). The first plate axis with size 1 is given just for clarity.

The prior for the ARD parameters α of the loading matrix:

```
>>> alpha = Gamma(1e-3, 1e-3,
... plates=(D,),
... name='alpha')
```

The prior for the loading matrix **C**:

```
>>> C = GaussianARD(0, alpha,
... shape=(D,),
... plates=(10,1),
... name='C')
```

Again, note that the shape is the same as for X for the same reason. Also, the plates of alpha, (D_r) , are mapped to the full shape of the node C, (10, 1, D), using standard broadcasting rules.

The dot product is just a deterministic node:

```
>>> F = Dot(C, X)
```

However, note that Dot requires that the input Gaussian nodes have the same shape and that this shape has exactly one axis, that is, the variables are vectors. This the reason why we used shape (D,) for X and C but from a bit different perspective. The node computes the inner product of D-dimensional vectors resulting in plates (10,100) broadcasted from the plates (1,100) and (10,1):

```
>>> F.plates (10, 100)
```

The prior for the observation noise τ :

```
>>> tau = Gamma(1e-3, 1e-3)
```

Finally, the observations are conditionally independent Gaussian scalars:

```
>>> Y = GaussianARD(F, tau)
```

Now we have defined our model and the next step is to observe some data and to perform inference.

2.4 Performing inference

Approximation of the posterior distribution can be divided into several steps:

- Observe some nodes
- Choose the inference engine
- Initialize the posterior approximation
- Run the inference algorithm

In order to illustrate these steps, we'll be using the PCA model constructed in the previous section.

2.4.1 Observing nodes

First, let us generate some toy data:

```
>>> c = np.random.randn(10, 2)

>>> x = np.random.randn(2, 100)

>>> data = np.dot(c, x) + 0.1*np.random.randn()
```

The data is provided by simply calling observe method of a stochastic node:

```
>>> Y.observe(data)
```

It is important that the shape of the data array matches the plates and shape of the node Y. For instance, if Y was Wishart node for 3×3 matrices with plates (5, 1, 10), the full shape of Y would be (5, 1, 10, 3, 3). The data array should have this shape exactly, that is, no broadcasting rules are applied.

Missing values

It is possible to mark missing values by providing a mask which is a boolean array:

```
>>> Y.observe(data, mask=[[True], [False], [False], [True], [True], ... [False], [True], [True], [True], [False]])
```

True means that the value is observed and False means that the value is missing. The shape of the above mask is (10, 1), which broadcasts to the plates of Y, (10, 100). Thus, the above mask means that the second, third, sixth and tenth rows of the 10×100 data matrix are missing.

The mask is applied to the *plates*, not to the data array directly. This means that it is not possible to observe a random variable partially, each repetition defined by the plates is either fully observed or fully missing. Thus, the mask is applied to the plates. It is often possible to circumvent this seemingly tight restriction by adding an observable child node which factorizes more.

The shape of the mask is broadcasted to plates using standard NumPy broadcasting rules. So, if the variable has plates (5,1,10), the mask could have a shape (),(1,),(1,1),(1,1,1),(10,),(1,10),(1,10),(5,1,1) or (5,1,10). In order to speed up the inference, missing values are automatically integrated out if they are not needed as latent variables to child nodes. This leads to faster convergence and more accurate approximations.

2.4.2 Choosing the inference method

Inference methods can be found in bayespy.inference package. Currently, only variational Bayesian approximation is implemented (bayespy.inference.VB). The inference engine is constructed by giving the stochastic nodes of the model.

```
>>> from bayespy.inference import VB
>>> Q = VB(Y, C, X, alpha, tau)
```

There is no need to give any deterministic nodes. Currently, the inference engine does not automatically search for stochastic parents and children, thus it is important that all stochastic nodes of the model are given. This should be made more robust in future versions.

A node of the model can be obtained by using the name of the node as a key:

```
>>> Q['X']
<bayespy.inference.vmp.nodes.gaussian.GaussianARD object at 0x...>
```

Note that the returned object is the same as the node object itself:

```
>>> Q['X'] is X True
```

Thus, one may use the object X when it is available. However, if the model and the inference engine are constructed in another function or module, the node object may not be available directly and this feature becomes useful.

2.4.3 Initializing the posterior approximation

The inference engines give some initialization to the stochastic nodes by default. However, the inference algorithms can be sensitive to the initialization, thus it is sometimes necessary to have better control over the initialization. For VB, the following initialization methods are available:

- initialize_from_prior: Use the current states of the parent nodes to update the node. This is the default initialization.
- initialize_from_parameters: Use the given parameter values for the distribution.
- initialize_from_value: Use the given value for the variable.
- initialize_from_random: Draw a random value for the variable. The random sample is drawn from the current state of the node's distribution.

Note that initialize_from_value and initialize_from_random initialize the distribution with a value of the variable instead of parameters of the distribution. Thus, the distribution is actually a delta distribution with a peak on the value after the initialization. This state of the distribution does not have proper natural parameter values nor normalization, thus the VB lower bound terms are np.nan for this initial state.

These initialization methods can be used to perform even a bit more complex initializations. For instance, a Gaussian distribution could be initialized with a random mean and variance 0.1. In our PCA model, this can be obtained by

```
>>> X.initialize_from_parameters(np.random.randn(1, 100, D), 10)
```

Note that the shape of the random mean is the sum of the plates (1, 100) and the variable shape (D,). In addition, instead of variance, GaussianARD uses precision as the second parameter, thus we initialized the variance to $\frac{1}{10}$. This random initialization is important in our PCA model because the default initialization gives C and X zero mean. If the mean of the other variable was zero when the other is updated, the other variable gets zero mean too. This would lead to an update algorithm where both means remain zeros and effectively no latent space is found. Thus, it is important to give non-zero random initialization for X if C is updated before X the first time. It is typical that at least some nodes need be initialized with some randomness.

By default, nodes are initialized with the method initialize_from_prior. The method is not very time consuming but if for any reason you want to avoid that default initialization computation, you can provide initialize=False when creating the stochastic node. However, the node does not have a proper state in that case, which leads to errors in VB learning unless the distribution is initialized using the above methods.

2.4.4 Running the inference algorithm

The approximation methods are based on iterative algorithms, which can be run using update method. By default, it takes one iteration step updating all nodes once:

```
>>> Q.update()
Iteration 1: loglike=-9.022564e+02 (... seconds)
```

The order in which the nodes are updated is the same as the order in which the nodes were given when creating Q. If you want to change the order or update only some of the nodes, you can give as arguments the nodes you want to update and they are updated in the given order:

```
>>> Q.update(C, X)
Iteration 2: loglike=-8.300209e+02 (... seconds)
```

It is also possible to give the same node several times:

```
>>> Q.update(C, X, C, tau)
Iteration 3: loglike=-7.608389e+02 (... seconds)
```

Note that each call to update is counted as one iteration step although not variables are necessarily updated. Instead of doing one iteration step, repeat keyword argument can be used to perform several iteration steps:

```
>>> Q.update(repeat=10)

Iteration 4: loglike=-6.909768e+02 (... seconds)

Iteration 5: loglike=-5.975477e+02 (... seconds)

Iteration 6: loglike=-4.328053e+02 (... seconds)

Iteration 7: loglike=-2.802900e+02 (... seconds)

Iteration 8: loglike=-1.628321e+02 (... seconds)

Iteration 9: loglike=-9.664200e+01 (... seconds)

Iteration 10: loglike=-7.202233e+01 (... seconds)

Iteration 11: loglike=-6.580980e+01 (... seconds)

Iteration 12: loglike=-6.444844e+01 (... seconds)

Iteration 13: loglike=-6.400242e+01 (... seconds)
```

The VB algorithm stops automatically if it converges, that is, the relative change in the lower bound is below some threshold:

```
>>> Q.update(repeat=1000)
Iteration 14: loglike=-6.371002e+01 (... seconds)
...
Iteration 48: loglike=8.275500e+02 (... seconds)
Converged at iteration 48.
```

Now the algorithm stopped before taking 1000 iteration steps because it converged. The relative tolerance can be adjusted by providing tol keyword argument to the update method:

```
>>> Q.update(repeat=10000, tol=1e-6)
Iteration 49: loglike=8.275572e+02 (... seconds)
...
Iteration 1731: loglike=8.320980e+02 (... seconds)
Converged at iteration 1731.
```

This shows that making the tolerance smaller, may improve the result but it may also significantly increase the iteration steps until convergence.

Instead of using update method of the inference engine VB, it is possible to use the update methods of the nodes directly as

```
>>> C.update()
or
>>> Q['C'].update()
```

However, this is not recommended, because the update method of the inference engine VB is a wrapper which, in addition to calling the nodes' update methods, checks for convergence and does a few other useful minor things. But if for any reason these direct update methods are needed, they can be used.

Parameter expansion

Sometimes the VB algorithm converges very slowly. This may happen when the variables are strongly coupled in the true posterior but factorized in the approximate posterior. This coupling leads to zigzagging of the variational parameters which progresses slowly. One solution to this problem is to use parameter expansion. The idea is to add an auxiliary variable which parameterizes the posterior approximation of several variables. Then optimizing this auxiliary variable actually optimizes several posterior approximations jointly leading to faster convergence.

The parameter expansion is model specific. Currently in BayesPy, only state-space models have built-in parameter expansions available. These state-space models contain a variable which is a dot product of two variables (plus some

noise):

$$y = \mathbf{c}^T \mathbf{x} + \text{noise}$$

The parameter expansion can be motivated by noticing that we can add an auxiliary variable which rotates the variables c and x so that the dot product is unaffected:

$$y = \mathbf{c}^T \mathbf{x} + \text{noise} = \mathbf{c}^T \mathbf{R} \mathbf{R}^{-1} \mathbf{x} + \text{noise} = (\mathbf{R}^T \mathbf{c})^T (\mathbf{R}^{-1} \mathbf{x}) + \text{noise}$$

Now, applying this rotation to the posterior approximations $q(\mathbf{c})$ and $q(\mathbf{x})$, and optimizing the VB lower bound with respect to the rotation leads to parameterized joint optimization of \mathbf{c} and \mathbf{x} .

The available parameter expansion methods are in module transformations:

```
>>> from bayespy.inference.vmp import transformations
```

First, you create the rotation transformations for the two variables:

```
>>> rotX = transformations.RotateGaussianARD(X)
>>> rotC = transformations.RotateGaussianARD(C, alpha)
```

Here, the rotation for C provides the ARD parameters alpha so they are updated simultaneously. In addition to RotateGaussianARD, there are a few other built-in rotations defined, for instance, RotateGaussian and RotateGaussianMarkovChain. It is extremely important that the model satisfies the assumptions made by the rotation class and the user is mostly responsible for this. The optimizer for the rotations is constructed by giving the two rotations and the dimensionality of the rotated space:

```
>>> R = transformations.RotationOptimizer(rotC, rotX, D)
```

Now, calling rotate method will find optimal rotation and update the relevant nodes (X, C and alpha) accordingly:

```
>>> R.rotate()
```

Let us see how our iteration would have gone if we had used this parameter expansion. First, let us re-initialize our nodes and VB algorithm:

```
>>> alpha.initialize_from_prior()
>>> C.initialize_from_prior()
>>> X.initialize_from_parameters(np.random.randn(1, 100, D), 10)
>>> tau.initialize_from_prior()
>>> Q = VB(Y, C, X, alpha, tau)
```

Then, the rotation is set to run after each iteration step:

```
>>> Q.callback = R.rotate
```

Now the iteration converges to the relative tolerance 10^{-6} much faster:

```
>>> Q.update(repeat=1000, tol=1e-6)
Iteration 1: loglike=-9.360795e+02 (... seconds)
...
Iteration 20: loglike=-2.962718e+01 (... seconds)
Converged at iteration 20.
```

However, the lower bound is worse than after converging to the same tolerance in 1731 iteration steps without the parameter expansion. To reach a better solution, we can force the VB algorithm to proceed for some iterations:

```
>>> Q.update(repeat=50, tol=np.nan)
Iteration 21: loglike=-2.962718e+01 (... seconds)
...
Iteration 70: loglike=8.560601e+02 (... seconds)
```

Now the iteration converged to a similar (actually slightly better) lower bound than before and much faster: 70 iterations versus 1731 iterations. One can compare the number of iteration steps in this case because the cost per iteration step with or without parameter expansion is approximately the same. However, this shows that the parameter expansion can have the drawback that it converges much faster but may converge to a bad local optimum more easily. Usually, this can solved by updating the nodes near the observations a few times before starting to update the hyperparameters and to use parameter expansion. In any case, the parameter expansion is practically necessary when using state-space models in order to converge to a proper solution in a reasonable time.

2.5 Examining the results

After the results have been obtained, it is important to be able to examine the results easily. show method prints the approximate posterior distribution of the node. Also, get_moments can be used to obtain the sufficient statistics of the node.

Todo

In order to examine the results more carefully, get_parameters method should return the parameter values of the approximate posterior distribution. The user may use these values for arbitrarily complex further analysis.

3.4 Discrete hidden Markov model

Iteration 3: loglike=nan (0.003 seconds)
Iteration 4: loglike=nan (0.003 seconds)

This example is also available as an IPython notebook or a Python script.

3.4.1 Known parameters

This example follows the one presented in Wikipedia. Each day, the state of the weather is either 'rainy' or 'sunny'. The weather follows a first-order discrete Markov process with the following initial state probability and state transition probabilities:

However, instead of observing this process directly, we observe whether Bob is 'walking', 'shopping' or 'cleaning'. The probability of each activity depends on the current weather as follows:

```
# Observed process
Y = Mixture(Z, Categorical, P)
```

In order to test our method, we'll generate artificial data using this model:

```
# Draw realization of the weather process
weather = Z.random()
# Using this weather, draw realizations of the activities
activity = Mixture(weather, Categorical, P).random()
```

Now, using this data, we set our variable Y to be observed:

```
Y.observe(activity)
```

In order to run inference, we construct variational Bayesian inference engine:

```
from bayespy.inference import VB
Q = VB(Y, Z)
```

Note that we need to give all random variables to VB. In this case, the only random variables were Y and Z. Next we run the inference, that is, compute our posterior distribution:

```
Q.update()
Iteration 1: loglike=-1.091583e+03 (0.090 seconds)
```

In this case, because there is only one unobserved random variable, we recover the exact posterior distribution and there is no need to iterate more than one step.

3.4.2 Unknown parameters

Next, we consider the case when we do not know the parameters of the weather process (initial state probability and state transition probabilities). We give these parameters quite non-informative priors, but it is possible to provide more informative priors if such information is available. First, the weather process:

Second, the emission probabilities are also given quite non-informative priors:

We use the same data as before:

```
Y.observe(activity)
```

Because VB takes all the unknown variables, we need to provide A, a0 and P also:

```
Q = VB(Y, Z, A, a0, P)
```

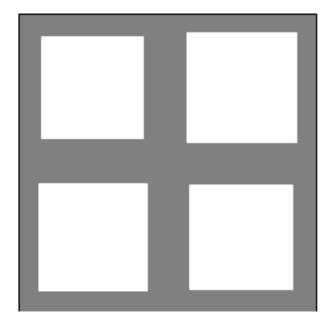

If we ran the VB algorithm now, we would get a result where all both states would have identical emission probability distribution. This happens because of a non-random default initialization. P is initialized in such a way that both states have the same distribution, and Z is initialized in such a way that each state has equal probability. Thus, the VB algorithm won't separate them. In such cases, it is necessary to use a random initialization. In principle, it is possible to use random initialization for either variable and then update the other variable first. In the case of mixture distributions, it might be better to initialize the parameters (P) randomly and update the state assignments (Z) first.

```
P.initialize_from_random()
Q.update(Z, A, a0, P, repeat=20)
Iteration 1: loglike=-1.115941e+03 (0.090 seconds)
Iteration 2: loglike=-1.115671e+03 (0.090 seconds)
Iteration 3: loglike=-1.115603e+03 (0.100 seconds)
Iteration 4: loglike=-1.115574e+03 (0.090 seconds)
Iteration 5: loglike=-1.115555e+03 (0.090 seconds)
Iteration 6: loglike=-1.115538e+03 (0.100 seconds)
Iteration 7: loglike=-1.115521e+03 (0.090 seconds)
Iteration 8: loglike=-1.115504e+03 (0.090 seconds)
Iteration 9: loglike=-1.115487e+03 (0.090 seconds)
Iteration 10: loglike=-1.115469e+03 (0.090 seconds)
Iteration 11: loglike=-1.115451e+03 (0.100 seconds)
Iteration 12: loglike=-1.115433e+03 (0.090 seconds)
Iteration 13: loglike=-1.115413e+03 (0.090 seconds)
Iteration 14: loglike=-1.115394e+03 (0.090 seconds)
Iteration 15: loglike=-1.115374e+03 (0.090 seconds)
Iteration 16: loglike=-1.115354e+03 (0.100 seconds)
Iteration 17: loglike=-1.115333e+03 (0.090 seconds)
Iteration 18: loglike=-1.115312e+03 (0.090 seconds)
Iteration 19: loglike=-1.115290e+03 (0.090 seconds)
Iteration 20: loglike=-1.115268e+03 (0.090 seconds)
```

In order to update the variables in that order, one may explicitly give the nodes in that order to the update method. However, the default update order is the one used when constructing Q, which is the same in this case, thus we could have ignored listing the nodes to the update method.

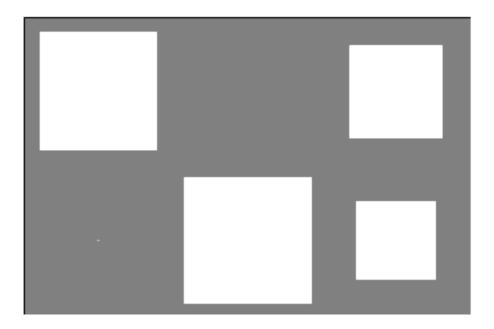

Plot the estimated state transition probabilities:

```
# NOTE: These three lines are just to enable inline plotting in IPython Notebooks.
import matplotlib.pyplot as plt
%matplotlib inline
plt.plot([])
# Plot the state transition matrix
import bayespy.plot.plotting as bpplt
bpplt.dirichlet_hinton(A)
```

Plot the estimated emission probabilities:

bpplt.dirichlet_hinton(P)

It is interesting that these estimated parameters are very different from the true parameters. This happens because of un-identifiability: different parameters lead to similar marginal distributions over the observed process.

3.5 Hidden Markov model

blaa blaa

3.6 Principal component analysis

Yeah.

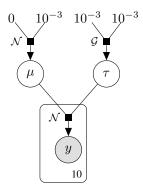

Figure 3.1: Directed factor graph of the example model.

```
from bayespy.nodes import GaussianARD
GaussianARD(0, 1)
<br/>
<br/>
<br/>
<br/>
daussianARD at 0x7fa3343bce90>
```

3.7 Linear state-space model

This example is also available as an IPython notebook or a Python script.

In linear state-space models a sequence of M-dimensional observations $\mathbf{Y} = (\mathbf{y}_1, \dots, \mathbf{y}_N)$ is assumed to be generated from latent D-dimensional states $\mathbf{X} = (\mathbf{x}_1, \dots, \mathbf{x}_N)$ which follow a first-order Markov process:

$$\mathbf{x}_n = \mathbf{A}\mathbf{x}_{n-1} + \text{noise},$$

 $\mathbf{y}_n = \mathbf{C}\mathbf{x}_n + \text{noise},$

where the noise is Gaussian, A is the $D \times D$ state dynamics matrix and C is the $M \times D$ loading matrix. Usually, the latent space dimensionality D is assumed to be much smaller than the observation space dimensionality M in order to model the dependencies of high-dimensional observations efficiently.

First, let us generate some toy data:

```
0,
                                      0, 0]])
              [0,
c = np.random.randn(M, 4)
x = np.empty((N, 4))
f = np.empty((M,N))
y = np.empty((M,N))
x[0] = 10*np.random.randn(4)
f[:,0] = np.dot(c,x[0])
y[:,0] = f[:,0] + 3*np.random.randn(M)
for n in range (N-1):
    x[n+1] = np.dot(a,x[n]) + np.random.randn(4)
    f[:,n+1] = np.dot(c,x[n+1])
    y[:,n+1] = f[:,n+1] + 3*np.random.randn(M)
The linear state-space model can be constructed as follows:
from bayespy.inference.vmp.nodes.gaussian_markov_chain import GaussianMarkovChain
from bayespy.inference.vmp.nodes.gaussian import GaussianARD
from bayespy.inference.vmp.nodes.gamma import Gamma
from bayespy.inference.vmp.nodes.dot import SumMultiply
D = 10
# Dynamics matrix with ARD
alpha = Gamma(1e-5,
              1e-5,
              plates=(D,),
              name='alpha')
A = GaussianARD(0,
                alpha,
                shape=(D,),
                plates=(D,),
                name='A')
# Latent states with dynamics
X = GaussianMarkovChain(np.zeros(D),
                                             # mean of x0
                        1e-3*np.identity(D), # prec of x0
                                              # dynamics
                        np.ones(D),
                                             # innovation
                        n=N,
                                              # time instances
                        name='X',
                        initialize=False)
X.initialize_from_value(np.zeros((N,D))) # just some empty values, X is
                                          # updated first anyway
# Mixing matrix from latent space to observation space using ARD
gamma = Gamma(1e-5,
              1e-5,
              plates=(D,),
              name='gamma')
C = GaussianARD(0,
                gamma,
                shape=(D,),
                plates=(M, 1),
                name='C')
# Initialize nodes (must use some randomness for C, and update X before C)
C.initialize_from_random()
# Observation noise
```

An inference machine using variational Bayesian inference with variational message passing is then construced as

```
from bayespy.inference.vmp.vmp import VB
Q = VB(X, C, gamma, A, alpha, tau, Y)
```

Observe the data partially (80% is marked missing):

```
from bayespy.utils import random
```

```
# Add missing values randomly (keep only 20%)
mask = random.mask(M, N, p=0.2)
Y.observe(y, mask=mask)
```

Then inference (100 iterations) can be run simply as

```
Q.update(repeat=10)
```

```
Iteration 1: loglike=-3.118644e+04 (0.210 seconds)
Iteration 2: loglike=-1.129540e+04 (0.210 seconds)
Iteration 3: loglike=-9.139376e+03 (0.210 seconds)
Iteration 4: loglike=-8.704676e+03 (0.220 seconds)
Iteration 5: loglike=-8.531889e+03 (0.200 seconds)
Iteration 6: loglike=-8.386198e+03 (0.210 seconds)
Iteration 7: loglike=-8.255826e+03 (0.210 seconds)
Iteration 8: loglike=-8.176274e+03 (0.210 seconds)
Iteration 9: loglike=-8.139579e+03 (0.210 seconds)
Iteration 10: loglike=-8.117779e+03 (0.210 seconds)
```

3.7.1 Speeding up with parameter expansion

VB inference can converge extremely slowly if the variables are strongly coupled. Because VMP updates one variable at a time, it may lead to slow zigzagging. This can be solved by using parameter expansion which reduces the coupling. In state-space models, the states \mathbf{x}_n and the loadings \mathbf{C} are coupled through a dot product $\mathbf{C}\mathbf{x}_n$, which is unaltered if the latent space is rotated arbitrarily:

$$\mathbf{y}_n = \mathbf{C}\mathbf{x}_n = \mathbf{C}\mathbf{R}^{-1}\mathbf{R}\mathbf{x}_n$$
.

Thus, one intuitive transformation would be $C \to CR^{-1}$ and $X \to RX$. In order to keep the dynamics of the latent states unaffected by the transformation, the state dynamics matrix **A** must be transformed accordingly:

$$\mathbf{R}\mathbf{x}_n = \mathbf{R}\mathbf{A}\mathbf{R}^{-1}\mathbf{R}\mathbf{x}_{n-1}$$
,

resulting in a transformation $A \to RAR^{-1}$. For more details, refer to *Fast Variational Bayesian Linear State-Space Model (Luttinen, 2013).

In BayesPy, the transformations can be used as follows:

```
# Import the parameter expansion module
from bayespy.inference.vmp import transformations

# Rotator of the state dynamics matrix
rotA = transformations.RotateGaussianARD(Q['A'], Q['alpha'])
# Rotator of the states (includes rotation of the state dynamics matrix)
rotX = transformations.RotateGaussianMarkovChain(Q['X'], rotA)
# Rotator of the loading matrix
rotC = transformations.RotateGaussianARD(Q['C'], Q['gamma'])
# Rotation optimizer
R = transformations.RotationOptimizer(rotX, rotC, D)
```

Note that it is crucial to select the correct rotation class which corresponds to the particular model block exactly. The rotation can be performed after each full VB update:

```
for ind in range(10):
    Q.update()
    R.rotate()

Iteration 11: loglike=-8.100983e+03 (0.210 seconds)
Iteration 12: loglike=-7.622913e+03 (0.210 seconds)
Iteration 13: loglike=-7.452057e+03 (0.200 seconds)
Iteration 14: loglike=-7.385975e+03 (0.200 seconds)
Iteration 15: loglike=-7.351449e+03 (0.210 seconds)
Iteration 16: loglike=-7.331026e+03 (0.210 seconds)
Iteration 17: loglike=-7.317997e+03 (0.200 seconds)
Iteration 18: loglike=-7.309212e+03 (0.200 seconds)
Iteration 19: loglike=-7.303074e+03 (0.210 seconds)
Iteration 20: loglike=-7.298661e+03 (0.210 seconds)
```

If you want to implement your own rotations or check the existing ones, you may use debugging utilities:

Gradient relative error = 6.78117e-05 and absolute error = 0.270191

Iteration 24: loglike=-7.289243e+03 (0.210 seconds)

Norm of numerical gradient: 13053.7

DEVELOPER GUIDE

How to document: https://github.com/numpy/numpy/blob/master/doc/HOWTO_DOCUMENT.rst.txt

How to contribute: http://docs.scipy.org/doc/numpy/dev/gitwash/development_workflow.html

4.1 Variational message passing

The general update equation for factorized approximation:

$$\log q(\boldsymbol{\theta}) = \langle \log p(\boldsymbol{\theta}|\operatorname{pa}(\boldsymbol{\theta})) \rangle + \sum_{\mathbf{x} \in \operatorname{ch}(\boldsymbol{\theta})} \langle \log p(\mathbf{x}|\operatorname{pa}(\mathbf{x})) \rangle + \operatorname{const}, \tag{4.1}$$

where $pa(\theta)$ and $ch(\theta)$ are the set of parents and children of θ , respectively. The expectations are over the approximate distribution of all other variables than θ . Actually, not all the variables are needed, because the non-constant part uses only the Markov blanket of θ . Thus, the optimization can be done locally using messages from neighbouring nodes.

The messages are simple for conjugate-exponential models. Exponential-family distributions have the form

$$\log p(\mathbf{x}|\mathbf{\Theta}) = \mathbf{u}_{\mathbf{x}}(\mathbf{x})^{\mathrm{T}} \boldsymbol{\phi}_{\mathbf{x}}(\mathbf{\Theta}) + g_{\mathbf{x}}(\mathbf{\Theta}) + f_{\mathbf{x}}(\mathbf{x}), \tag{4.2}$$

where $\Theta = \{\theta_j\}$ is the set of parents. If a parent has a conjugate prior, (4.2) is linear with respect to the parent's natural statistics. Thus, (4.2) can be re-organized with respect to θ_j as

$$\log p(\mathbf{x}|\mathbf{\Theta}) = \mathbf{u}_{\boldsymbol{\theta}_j}(\boldsymbol{\theta}_j)^{\mathrm{T}} \boldsymbol{\phi}_{\mathbf{x} \to \boldsymbol{\theta}_j}(\mathbf{x}, \{\boldsymbol{\theta}_k\}_{k \neq j}) + \text{const},$$

where \mathbf{u}_{θ_j} is the natural statistics of θ_j . Thus, the update equation (4.1) can be given as

$$\log q(\boldsymbol{\theta}_j) = \mathbf{u}_{\boldsymbol{\theta}_j}(\boldsymbol{\theta}_j)^{\mathrm{T}} \left(\langle \boldsymbol{\phi}_{\boldsymbol{\theta}_j} \rangle + \sum_{\mathbf{x} \in \mathrm{ch}(\boldsymbol{\theta}_j)} \langle \boldsymbol{\phi}_{\mathbf{x} \to \boldsymbol{\theta}_j} \rangle \right) + f_{\boldsymbol{\theta}_j}(\boldsymbol{\theta}_j) + \mathrm{const},$$

where the summation is over all the child nodes of θ_j . Because of the conjugacy, $\langle \phi_{\theta_j} \rangle$ depends (multi)linearly on the expectations of the parents' natural statistics. Similarly, $\langle \phi_{\mathbf{x} \to \theta_j} \rangle$ depends (multi)linearly on the expectations of the children's and co-parents' natural statistics.

The required expectations can be computed locally by using messages from the parents and the children. The message from a parent node θ_i to a child node x is

$$\mathbf{m}_{\boldsymbol{\theta}_{\mathbf{j}} \rightarrow \mathbf{x}} = \langle \mathbf{u}_{\boldsymbol{\theta}_{j}} \rangle = \tilde{\mathbf{u}}_{\boldsymbol{\theta}_{j}} (\tilde{\boldsymbol{\phi}}_{\boldsymbol{\theta}_{\mathbf{j}}}),$$

and the message from a child node x to a parent node θ_i is

$$\mathbf{m}_{\mathbf{x} \rightarrow \boldsymbol{\theta}_j} = \langle \boldsymbol{\phi}_{\mathbf{x} \rightarrow \boldsymbol{\theta}_j} \rangle = \boldsymbol{\phi}_{\mathbf{x} \rightarrow \boldsymbol{\theta}_j} \left(\langle \mathbf{u}_{\mathbf{x}} \rangle, \{ \mathbf{m}_{\boldsymbol{\theta}_k \rightarrow \mathbf{x}} \}_{k \neq j} \right).$$

Using the messages, the natural parameters of $q(\theta)$ can be updated as

$$\tilde{\phi}_{\boldsymbol{\theta}} = \phi_{\boldsymbol{\theta}} \left(\{ \mathbf{m}_{\mathbf{z} \rightarrow \boldsymbol{\theta}} \}_{\mathbf{z} \in \mathrm{pa}(\boldsymbol{\theta})} \right) + \sum_{\mathbf{x} \in \mathrm{ch}(\boldsymbol{\theta})} \mathbf{m}_{\mathbf{x} \rightarrow \boldsymbol{\theta}}.$$

4.2 Implementing nodes

CHAPTER

FIVE

USER API

5.1 Nodes

5.1.1 Stochastic nodes

Nodes for Gaussian variables:

Gaussian(mu, Lambda, **kwargs)	Node for Gaussian variables.
<pre>GaussianARD(mu, alpha[, ndim, shape])</pre>	Node for Gaussian variables with ARD prior.

bayespy.nodes.Gaussian

class bayespy.nodes.Gaussian (mu, Lambda, **kwargs)

Node for Gaussian variables.

The node represents a D-dimensional vector from the Gaussian distribution:

$$\mathbf{x} \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Lambda}),$$

where μ is the mean vector and Λ is the precision matrix (i.e., inverse of the covariance matrix).

$$\mathbf{x}, \boldsymbol{\mu} \in \mathbb{R}^D$$
, $\boldsymbol{\Lambda} \in \mathbb{R}^{D \times D}$, $\boldsymbol{\Lambda}$ symmetric positive definite

Parameters mu: Gaussian-like node or GaussianGammaISO-like node or GaussianWishart-like node or array

Mean vector

Lambda: Wishart-like node or array

Precision matrix

See also:

Wishart, GaussianARD, GaussianWishart, GaussianGammaARD, GaussianGammaISO

Methods

add_plate_axis(to_plate)		
delete()	Delete this node and the children	
get_mask()

Delete this node and the children

bayespy.nodes.Gaussian.get_mask

```
Gaussian.get_mask()
```

bayespy.nodes.Gaussian.get_moments

```
Gaussian.get_moments()
```

bayespy.nodes.Gaussian.get_shape

```
Gaussian.get_shape (ind)
```

```
bayespy.nodes.Gaussian.has plotter
Gaussian.has_plotter()
    Return True if the node has a plotter
bayespy.nodes.Gaussian.initialize from parameters
Gaussian.initialize_from_parameters(mu, Lambda)
bayespy.nodes.Gaussian.initialize_from_prior
Gaussian.initialize_from_prior()
bayespy.nodes.Gaussian.initialize from random
Gaussian.initialize_from_random()
    Set the variable to a random sample from the current distribution.
bayespy.nodes.Gaussian.initialize from value
Gaussian.initialize_from_value(x, *args)
bayespy.nodes.Gaussian.load
Gaussian.load(group)
    Load the state of the node from a HDF5 file.
bayespy.nodes.Gaussian.logpdf
Gaussian.logpdf(X, mask=True)
    Compute the log probability density function Q(X) of this node.
bayespy.nodes.Gaussian.lower bound contribution
Gaussian.lower_bound_contribution(gradient=False)
bayespy.nodes.Gaussian.lowerbound
Gaussian.lowerbound()
bayespy.nodes.Gaussian.move_plates
Gaussian.move_plates (from_plate, to_plate)
```

bayespy.nodes.Gaussian.observe

```
Gaussian.observe(x, *args, mask=True)
```

Fix moments, compute f and propagate mask.

bayespy.nodes.Gaussian.pdf

```
Gaussian.pdf (X, mask=True)
```

Compute the probability density function of this node.

bayespy.nodes.Gaussian.plot

```
Gaussian.plot(**kwargs)
```

Plot the node distribution using the plotter of the node

Because the distributions are in general very difficult to plot, the user must specify some functions which performs the plotting as wanted. See, for instance, bayespy.plot.plotting for available plotters, that is, functions that perform plotting for a node.

bayespy.nodes.Gaussian.random

```
Gaussian.random()
```

Draw a random sample from the distribution.

bayespy.nodes.Gaussian.rotate

```
Gaussian.rotate(R, inv=None, logdet=None, Q=None)
```

bayespy.nodes.Gaussian.rotate_matrix

```
Gaussian.rotate_matrix(R1, R2, inv1=None, logdet1=None, inv2=None, logdet2=None, Q=None)
```

The vector is reshaped into a matrix by stacking the row vectors.

Computes R1*X*R2', which is identical to kron(R1,R2)*x (??)

Note that this is slightly different from the standard Kronecker product definition because Numpy stacks row vectors instead of column vectors.

Parameters R1: ndarray

A matrix from the left

R2: ndarray

A matrix from the right

bayespy.nodes.Gaussian.save

```
Gaussian.save(group)
```

Save the state of the node into a HDF5 file.

group can be the root

bayespy.nodes.Gaussian.set plotter

Gaussian.set_plotter(plotter)

bayespy.nodes.Gaussian.show

Gaussian.show()

bayespy.nodes.Gaussian.unobserve

Gaussian.unobserve()

bayespy.nodes.Gaussian.update

Gaussian.update()

Attributes

dims plates

bayespy.nodes.Gaussian.dims

Gaussian.dims = None

bayespy.nodes.Gaussian.plates

Gaussian.plates = None

bayespy.nodes.GaussianARD

class bayespy.nodes.**GaussianARD** (*mu*, *alpha*, *ndim=None*, *shape=None*, **kwargs) Node for Gaussian variables with ARD prior.

The node represents a *D*-dimensional vector from the Gaussian distribution:

$$\mathbf{x} \sim \mathcal{N}(\boldsymbol{\mu}, \operatorname{diag}(\boldsymbol{\alpha})),$$

where μ is the mean vector and diag(α) is the diagonal precision matrix (i.e., inverse of the covariance matrix).

$$\mathbf{x}, \boldsymbol{\mu} \in \mathbb{R}^D$$
, $\alpha_d > 0$ for $d = 0, \dots, D-1$

Note: The form of the posterior approximation is a Gaussian distribution with full covariance matrix instead of a diagonal matrix.

Parameters mu: Gaussian-like node or GaussianGammaISO-like node or GaussianGammaARD-like node or array

Mean vector

alpha: gamma-like node or array

Diagonal elements of the precision matrix

See also:

Gamma, Gaussian, GaussianGammaARD, GaussianGammaISO, GaussianWishart

GaussianARD.get_moments()
bayespy.nodes.GaussianARD.get shape
GaussianARD.get_shape(ind)
bayespy.nodes.GaussianARD.has_plotter
GaussianARD.has_plotter()
    Return True if the node has a plotter
bayespy.nodes.GaussianARD.initialize_from_mean_and_covariance
GaussianARD.initialize_from_mean_and_covariance(mu, Cov)
bayespy.nodes.GaussianARD.initialize from parameters
GaussianARD.initialize from parameters (mu, alpha)
bayespy.nodes.GaussianARD.initialize_from_prior
GaussianARD.initialize_from_prior()
bayespy.nodes.GaussianARD.initialize from random
GaussianARD.initialize_from_random()
    Set the variable to a random sample from the current distribution.
bayespy.nodes.GaussianARD.initialize from value
GaussianARD.initialize_from_value(x, *args)
bayespy.nodes.GaussianARD.load
GaussianARD.load(group)
    Load the state of the node from a HDF5 file.
bayespy.nodes.GaussianARD.logpdf
GaussianARD.logpdf(X, mask=True)
    Compute the log probability density function Q(X) of this node.
```

bayespy.nodes.GaussianARD.lower bound contribution

GaussianARD.lower_bound_contribution(gradient=False)

bayespy.nodes.GaussianARD.lowerbound

GaussianARD.lowerbound()

bayespy.nodes.GaussianARD.move_plates

GaussianARD.move_plates (from_plate, to_plate)

bayespy.nodes.GaussianARD.observe

```
GaussianARD.observe (x, *args, mask=True) Fix moments, compute f and propagate mask.
```

bayespy.nodes.GaussianARD.pdf

```
GaussianARD.pdf (X, mask=True)
```

Compute the probability density function of this node.

bayespy.nodes.GaussianARD.plot

```
GaussianARD.plot(**kwargs)
```

Plot the node distribution using the plotter of the node

Because the distributions are in general very difficult to plot, the user must specify some functions which performs the plotting as wanted. See, for instance, bayespy.plot.plotting for available plotters, that is, functions that perform plotting for a node.

bayespy.nodes.GaussianARD.random

```
GaussianARD.random()
```

Draw a random sample from the distribution.

bayespy.nodes.GaussianARD.rotate

```
GaussianARD.rotate(R, inv=None, logdet=None, axis=-1, Q=None)
```

$bayes py. nodes. Gaussian ARD. rotate_plates$

```
GaussianARD.rotate_plates (Q, plate_axis=-1)
```

Approximate rotation of a plate axis.

Mean is rotated exactly but covariance/precision matrix is rotated approximately.

bayespy.nodes.GaussianARD.save

```
\texttt{GaussianARD.save}\,(\textit{group})
```

Save the state of the node into a HDF5 file.

group can be the root

Gamma.save(group)
     Save the state of the node into a HDF5 file.
     group can be the root
bayespy.nodes.Gamma.set_plotter
Gamma.set_plotter(plotter)
```

bayespy.nodes.Gamma.show

Gamma.show()

Print the distribution using standard parameterization.

bayespy.nodes.Gamma.unobserve

Gamma.unobserve()

bayespy.nodes.Gamma.update

Gamma.update()

Attributes

dims	tuple() -> empty tuple
plates	

bayespy.nodes.Gamma.dims

Gamma.dims = ((), ())

bayespy.nodes.Gamma.plates

Gamma.plates = None

bayespy.nodes.Wishart

class bayespy.nodes.Wishart (n, V, **kwargs)

Node for Wishart random variables.

The random variable Λ is a $D \times D$ positive-definite symmetric matrix.

$$p(\mathbf{\Lambda}) = \text{Wishart}(\mathbf{\Lambda}|N, \mathbf{V})$$

Parameters n : scalar or array

N, degrees of freedom, N > D - 1.

V: Wishart-like node or (...,D,D)-array

V, scale matrix.

Methods

add_plate_axis(to_plate)
delete()

Delete this node and the children

```

bayespy.nodes.Exponential

```
class bayespy.nodes.Exponential (l, **kwargs)
Node for exponential random variables.
```

```
Warning: Use Gamma instead of this. Exponential(l) is equivalent to Gamma(1, l).
```

Parameters 1: gamma-like node or scalar or array

Rate parameter

See also:

Gamma, Poisson

Notes

For simplicity, this is just a gamma node with the first parent fixed to one. Note that this is a bit inconsistent with the BayesPy philosophy which states that the node does not only define the form of the prior distribution but more importantly the form of the posterior approximation. Thus, one might expect that this node would have exponential posterior distribution approximation. However, it has a gamma distribution. Also, the moments are gamma moments although only E[x] would be the moment of a exponential random variable. All this was done because: a) gamma was already implemented, so there was no need to implement anything, and b) people might easily use Exponential node as a prior definition and expect to get gamma posterior (which is what happens now). Maybe some day a pure Exponential node is implemented and the users are advised to use Gamma(1,b) if they want to use an exponential prior distribution but gamma posterior approximation.

Methods

```
add_plate_axis(to_plate)
as diagonal wishart()
delete()
                                           Delete this node and the children
get_mask()
get moments()
get shape(ind)

    Fix moments, compute f and propagate mask.
bayespy.nodes.Exponential.pdf
Exponential.pdf (X, mask=True)
    Compute the probability density function of this node.
```

bayespy.nodes.Exponential.plot

```
Exponential.plot(**kwargs)
```

Plot the node distribution using the plotter of the node

Because the distributions are in general very difficult to plot, the user must specify some functions which performs the plotting as wanted. See, for instance, bayespy.plot.plotting for available plotters, that is, functions that perform plotting for a node.

bayespy.nodes.Exponential.random

```
Exponential.random()
```

Draw a random sample from the distribution.

bayespy.nodes.Exponential.save

```
Exponential.save(group)
```

Save the state of the node into a HDF5 file.

group can be the root

bayespy.nodes.Exponential.set_plotter

```
Exponential.set_plotter(plotter)
```

bayespy.nodes.Exponential.show

```
Exponential.show()
```

Print the distribution using standard parameterization.

bayespy.nodes.Exponential.unobserve

```
Exponential.unobserve()
```

bayespy.nodes.Exponential.update

```
Exponential.update()
```

Attributes

dims	tuple() -> empty tuple
plates	

bayespy.nodes.Exponential.dims

```
Exponential.dims = ((), ())
```

bayespy.nodes.Exponential.plates

```
Exponential.plates = None
```

Nodes for modelling Gaussian and precision variables jointly (useful as prior for Gaussian nodes):

```
GaussianGammaISO(*args, **kwargs)
GaussianGammaARD(mu, alpha, a, b, **kwargs)
GaussianWishart(*args, **kwargs)
Node for Gaussian-gamma (isotropic) random variables.
Node for Gaussian and gamma random variables with ARD form.
Node for Gaussian-Wishart random variables.
```

bayespy.nodes.GaussianGammalSO

```
class bayespy.nodes.GaussianGammaISO (*args, **kwargs)
    Node for Gaussian-gamma (isotropic) random variables.
```

The prior:

$$p(x, \alpha | \mu, \Lambda, a, b)$$

$$p(x | \alpha, \mu, \Lambda) = \mathcal{N}(x | \mu, \alpha Lambda)$$

$$p(\alpha | a, b) = \mathcal{G}(\alpha | a, b)$$

The posterior approximation $q(x, \alpha)$ has the same Gaussian-gamma form.

Currently, supports only vector variables.

Methods

```
add_plate_axis(to_plate)
                                              Delete this node and the children
delete()
get_gaussian_mean_and_variance()
                                              Return the mean and variance of the distribution
                                              Get the (marginal) log pdf of a subset of the variables

                                                                                 Continued on next page
```

Table 5.14 – continued from previous page

show()
unobserve()
update()

Print the distribution using standard parameterization.

bayespy.nodes.GaussianGammalSO.add plate axis

GaussianGammaISO.add_plate_axis(to_plate)

bayespy.nodes.GaussianGammalSO.delete

GaussianGammaISO.delete()

Delete this node and the children

$bayespy. nodes. Gaussian Gammal SO. get_gaussian_mean_and_variance$

GaussianGammaISO.get_gaussian_mean_and_variance()

Return the mean and variance of the distribution

bayespy.nodes.GaussianGammalSO.get_marginal_logpdf

GaussianGammaISO.get_marginal_logpdf(gaussian=None, gamma=None)
Get the (marginal) log pdf of a subset of the variables

Parameters gaussian: list or None

Indices of the Gaussian variables to keep or None

gamma: bool or None

True if keep the gamma variable, otherwise False or None

Returns function

A function which computes log-pdf

bayespy.nodes.GaussianGammalSO.get_mask

GaussianGammaISO.get_mask()

bayespy.nodes.GaussianGammalSO.get_moments

GaussianGammaISO.get_moments()

bayespy.nodes.GaussianGammalSO.get_shape

GaussianGammaISO.get_shape (ind)

```
GaussianGammaISO.has_plotter()
    Return True if the node has a plotter
bayespy.nodes.GaussianGammalSO.initialize from parameters
GaussianGammaISO.initialize_from_parameters(*args)
bayespy.nodes.GaussianGammalSO.initialize_from_prior
GaussianGammaISO.initialize_from_prior()
bayespy.nodes.GaussianGammalSO.initialize from random
GaussianGammaISO.initialize_from_random()
    Set the variable to a random sample from the current distribution.
bayespy.nodes.GaussianGammalSO.initialize from value
GaussianGammaISO.initialize_from_value(x, *args)
bayespy.nodes.GaussianGammalSO.load
GaussianGammaISO.load(group)
    Load the state of the node from a HDF5 file.
bayespy.nodes.GaussianGammalSO.logpdf
GaussianGammaISO.logpdf(X, mask=True)
    Compute the log probability density function Q(X) of this node.
bayespy.nodes.GaussianGammalSO.lower bound contribution
GaussianGammaISO.lower_bound_contribution(gradient=False)
bayespy.nodes.GaussianGammalSO.lowerbound
GaussianGammaISO.lowerbound()
bayespy.nodes.GaussianGammalSO.move_plates
GaussianGammaISO.move_plates (from_plate, to_plate)
```

bayespy.nodes.GaussianGammalSO.has_plotter

bayespy.nodes.GaussianGammalSO.observe

```
GaussianGammaISO.observe (x, *args, mask=True) Fix moments, compute f and propagate mask.
```

bayespy.nodes.GaussianGammalSO.pdf

```
GaussianGammaISO.pdf (X, mask=True)
```

Compute the probability density function of this node.

bayespy.nodes.GaussianGammalSO.plot

```
GaussianGammaISO.plot (**kwargs)
```

Plot the node distribution using the plotter of the node

Because the distributions are in general very difficult to plot, the user must specify some functions which performs the plotting as wanted. See, for instance, bayespy.plot.plotting for available plotters, that is, functions that perform plotting for a node.

bayespy.nodes.GaussianGammalSO.plotmatrix

```
GaussianGammaISO.plotmatrix()
```

Creates a matrix of marginal plots.

On diagonal, are marginal plots of each variable. Off-diagonal plot (i,j) shows the joint marginal density of x_i and x_j .

bayespy.nodes.GaussianGammalSO.random

```
GaussianGammaISO.random()
```

Draw a random sample from the distribution.

bayespy.nodes.GaussianGammalSO.save

```
GaussianGammaISO.save (group)
```

Save the state of the node into a HDF5 file.

group can be the root

bayespy.nodes.GaussianGammalSO.set_plotter

```
GaussianGammaISO.set_plotter(plotter)
```

bayespy.nodes.GaussianGammalSO.show

```
GaussianGammaISO.show()
```

Print the distribution using standard parameterization.

bayespy.nodes.GaussianGammalSO.unobserve

GaussianGammaISO.unobserve()

bayespy.nodes.GaussianGammalSO.update

GaussianGammaISO.update()

Attributes

dims plates

bayespy.nodes.GaussianGammalSO.dims

bayespy.nodes.GaussianGammalSO.plates

GaussianGammaISO.plates = None

bayespy.nodes.GaussianGammaARD

 $\textbf{class} \ \texttt{bayespy.nodes.GaussianGammaARD} \ (\textit{mu}, \textit{alpha}, \textit{a}, \textit{b}, **kwargs)$

Node for Gaussian and gamma random variables with ARD form.

The prior:

$$p(x,\tau|\mu,\alpha,a,b) = p(x|\tau,\mu,\alpha)p(\tau|a,b)$$
$$p(x|\alpha,\mu,\alpha) = \mathcal{N}(x|\mu,\mathrm{diag}(\alpha \tau))$$
$$p(\tau|a,b) = \mathcal{G}(\tau|a,b)$$

The posterior approximation $q(x,\tau)$ has the same Gaussian-gamma form.

Warning: Not yet implemented.

See also:

 ${\tt Gaussian, Gaussian ARD, Gamma, Gaussian Gamma ISO, Gaussian Wishart}$

bayespy.nodes.GaussianGammaARD.plates

GaussianGammaARD.plates = None

bayespy.nodes.GaussianWishart

```
class bayespy.nodes.GaussianWishart(*args, **kwargs)
```

Node for Gaussian-Wishart random variables.

The prior:

$$p(x, \Lambda | \mu, \alpha, V, n)$$

$$p(x | \Lambda, \mu, \alpha) = (N)(x | \mu, \alpha^{-1} Lambda^{-1})$$

$$p(\Lambda | V, n) = (W)(\Lambda | n, V)$$

The posterior approximation $q(x, \Lambda)$ has the same Gaussian-Wishart form.

Currently, supports only vector variables.

Methods

```

```
GaussianWishart.unobserve()
```

bayespy.nodes.GaussianWishart.update

```
GaussianWishart.update()
```

Attributes

```
dims plates
```

bayespy.nodes.GaussianWishart.dims

GaussianWishart.dims = None

bayespy.nodes.GaussianWishart.plates

GaussianWishart.plates = None

Nodes for discrete count variables:

Bernoulli(p, **kwargs)	Node for Bernoulli random variables.
Binomial(n, p, **kwargs)	Node for binomial random variables.
Categorical(p, **kwargs)	Node for categorical random variables.
<pre>Multinomial(n, p, **kwargs)</pre>	Node for multinomial random variables.
Poisson(l, **kwargs)	Node for Poisson random variables.

bayespy.nodes.Bernoulli

```
{f class} bayespy.nodes.Bernoulli(p,\ ^{**}kwargs)
```

Node for Bernoulli random variables.

The node models a binary random variable $z \in \{0, 1\}$ with prior probability $p \in [0, 1]$ for value one:

 $z \sim \text{Bernoulli}(p)$.

Parameters p: beta-like node

Probability of a successful trial

Examples

```
from bayespy.nodes import Bernoulli, Beta
p = Beta([1e-3, 1e-3])
z = Bernoulli(p, plates=(10,))
z.observe([0, 1, 1, 1, 0, 1, 1, 1, 0, 1])
p.update()
import bayespy.plot as bpplt
import numpy as np
bpplt.pdf(p, np.linspace(0, 1, num=100))
```

Methods

```
add_plate_axis(to_plate)
delete()
                                             Delete this node and the children

```

bayespy.nodes.Bernoulli.plates

```
Bernoulli.plates = None
```

bayespy.nodes.Binomial

```
class bayespy.nodes.Binomial(n, p, **kwargs)
```

Node for binomial random variables.

The node models the number of successes $x \in \{0, \dots, n\}$ in n trials with probability p for success:

```
x \sim \text{Binomial}(n, p).
```

Parameters n : scalar or array

Number of trials

p: beta-like node or scalar or array

Probability of a success in a trial

See also:

```
Bernoulli, Multinomial, Beta
```

Examples

```
from bayespy.nodes import Binomial, Beta
p = Beta([1e-3, 1e-3])
x = Binomial(10, p)
x.observe(7)
p.update()
import bayespy.plot as bpplt
import numpy as np
bpplt.pdf(p, np.linspace(0, 1, num=100))
```

Methods

```
add_plate_axis(to_plate)

bayespy.nodes.Categorical

class bayespy.nodes.Categorical(p, **kwargs)

Node for categorical random variables.

The node models a categorical random variable $x \in \{0, \dots, K-1\}$ with prior probabilities $\{p_0, \dots, p_{K-1}\}$ for each category:

$$p(x = k) = p_k$$
 for $k \in \{0, \dots, K - 1\}$.

Parameters p: Dirichlet-like node or (...,K)-array

Probabilities for each category

Categorical.plates = None
```

bayespy.nodes.Multinomial

```
class bayespy.nodes.Multinomial(n, p, **kwargs)
```

Node for multinomial random variables.

Assume there are K categories and N trials each of which leads a success for exactly one of the categories. Given the probabilities p_0, \ldots, p_{K-1} for the categories, multinomial distribution is gives the probability of any combination of numbers of successes for the categories.

The node models the number of successes $x_k \in \{0, ..., n\}$ in n trials with probability p_k for success in K categories.

$$\operatorname{Multinomial}(\mathbf{x}|N,\mathbf{p}) = \frac{N!}{x_0! \cdots x_{K-1}!} p_0^{x_0} \cdots p_{K-1}^{x_{K-1}}$$

Parameters n: scalar or array

N, number of trials

p: Dirichlet-like node or (...,K)-array

p, probabilities of successes for the categories

See also:

Dirichlet, Binomial, Categorical

```
Multinomial.plates = None
```

bayespy.nodes.Poisson

```
class bayespy.nodes.Poisson (l, **kwargs)
    Node for Poisson random variables.
```

The node uses Poisson distribution:

 $p(x) = Poisson(x|\lambda)$

where λ is the rate parameter.

Parameters 1: gamma-like node or scalar or array

 λ , rate parameter

See also:

Gamma, Exponential

Poisson.dims = ((),)
```

bayespy.nodes.Poisson.plates

```
Poisson.plates = None
```

Nodes for probabilities:

Beta(alpha, **kwargs)	Node for beta random variables.
Dirichlet(*args, **kwargs)	Node for Dirichlet random variables.

bayespy.nodes.Beta

```
class bayespy.nodes.Beta (alpha, **kwargs)
```

Node for beta random variables.

The node models a probability variable $p \in [0, 1]$ as

 $p \sim \text{Beta}(a, b)$

where a and b are prior counts for success and failure, respectively.

Parameters alpha: (...,2)-shaped array

Two-element vector containing a and b

Examples

```
from bayespy.nodes import Bernoulli, Beta
p = Beta([1e-3, 1e-3])
z = Bernoulli(p, plates=(10,))
z.observe([0, 1, 1, 1, 0, 1, 1, 1, 0, 1])
p.update()
import bayespy.plot as bpplt
import numpy as np
bpplt.pdf(p, np.linspace(0, 1, num=100))
```

Methods

```

bayespy.nodes.Beta.dims

Beta.dims = None

bayespy.nodes.Beta.plates

Beta.plates = None

bayespy.nodes.Dirichlet

class bayespy.nodes.Dirichlet(*args, **kwargs)

Node for Dirichlet random variables.

The node models a set of probabilities $\{\pi_0,\ldots,\pi_{K-1}\}$ which satisfy $\sum_{k=0}^{K-1}\pi_k=1$ and $\pi_k\in[0,1]$ $\forall k=0,\ldots,K-1$.

$$p(\pi_0, \ldots, \pi_{K-1}) = Dirichlet(\alpha_0, \ldots, \alpha_{K-1})$$

where α_k are concentration parameters.

The posterior approximation has the same functional form but with different concentration parameters.

Parameters alpha: (...,K)-shaped array

Prior counts α_k

Attributes

dims plates

bayespy.nodes.Dirichlet.dims

Dirichlet.dims = None

bayespy.nodes.Dirichlet.plates

Dirichlet.plates = None

Nodes for dynamic variables:

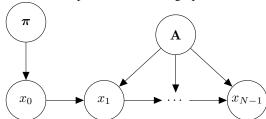

CategoricalMarkovChain(pi, A[, states])	Node for categorical Markov chain random variables.
<pre>GaussianMarkovChain(mu, Lambda, A, nu[, n])</pre>	Node for Gaussian Markov chain random variables.
SwitchingGaussianMarkovChain(mu, Lambda, B,)	Node for Gaussian Markov chain random variables with switching d
VaryingGaussianMarkovChain(mu, Lambda, B, S, nu)	Node for Gaussian Markov chain random variables with time-varying

bayespy.nodes.CategoricalMarkovChain

class bayespy.nodes.CategoricalMarkovChain(pi, A, states=None, **kwargs)

Node for categorical Markov chain random variables.

The node models a Markov chain which has a discrete set of K possible states and the next state depends only on the previous state and the state transition probabilities. The graphical model is shown below:

where π contains the probabilities for the initial state and A is the state transition probability matrix. It is possible to have A varying in time.

$$p(x_0, \dots, x_{N-1}) = p(x_0) \prod_{n=1}^{N-1} p(x_n | x_{n-1}),$$

where

$$p(x_0 = k) = \pi_k, \quad \text{for } k \in \{0, \dots, K - 1\},$$

$$p(x_n = j | x_{n-1} = i) = a_{ij}^{(n-1)} \quad \text{for } n = 1, \dots, N - 1, \ i \in \{1, \dots, K - 1\}, \ j \in \{1, \dots, K - 1\}$$

$$a_{ij}^{(n)} = [\mathbf{A}_n]_{ij}$$

This node can be used to construct hidden Markov models by using Mixture for the emission distribution.

Parameters pi: Dirichlet-like node or (...,K)-array

 π , probabilities for the first state. K-dimensional Dirichlet.

A: Dirichlet-like node or (K,K)-array or (...,1,K,K)-array or (...,N-1,K,K)-array

A, probabilities for state transitions. K-dimensional Dirichlet with plates (K,) or (...,1,K) or (...,N-1,K).

states: int, optional

N, the length of the chain.

bayespy.nodes.CategoricalMarkovChain.plates

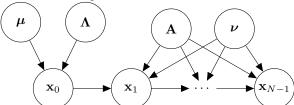

CategoricalMarkovChain.plates = None

bayespy.nodes.GaussianMarkovChain

class bayespy.nodes.GaussianMarkovChain (mu, Lambda, A, nu, n=None, **kwargs)

Node for Gaussian Markov chain random variables.

In a simple case, the graphical model can be presented as:

where μ and Λ are the mean and the precision matrix of the initial state, $\bf A$ is the state dynamics matrix and ν is the precision of the innovation noise. It is possible that $\bf A$ and/or ν are different for each transition instead of being constant.

The probability distribution is

$$p(\mathbf{x}_0, \dots, \mathbf{x}_{N-1}) = p(\mathbf{x}_0) \prod_{n=1}^{N-1} p(\mathbf{x}_n | \mathbf{x}_{n-1})$$

where

$$p(\mathbf{x}_0) = \mathcal{N}(\mathbf{x}_0 | \boldsymbol{\mu}, \boldsymbol{\Lambda})$$
$$p(\mathbf{x}_n | \mathbf{x}_{n-1}) = \mathcal{N}(\mathbf{x}_n | \mathbf{A}_{n-1} \mathbf{x}_{n-1}, \operatorname{diag}(\boldsymbol{\nu}_{n-1})).$$

Parameters mu: Gaussian-like node or (...,D)-array

 μ , mean of x_0 , D-dimensional with plates (...)

Lambda: Wishart-like node or (...,D,D)-array

 Λ , precision matrix of x_0 , $D \times D$ -dimensional with plates (...)

A: Gaussian-like node or (D,D)-array or (...,1,D,D)-array or (...,N-1,D,D)-array

A, state dynamics matrix, D-dimensional with plates (D,) or (...,1,D) or (...,N-1,D)

nu: gamma-like node or (D,)-array or (...,1,D)-array or (...,N-1,D)-array

 ν , diagonal elements of the precision of the innovation process, plates (D,) or (...,1,D) or (...,N-1,D)

n: int, optional

N, the length of the chain. Must be given if ${\bf A}$ and ${\bf \nu}$ are constant over time.

bayespy.nodes.GaussianMarkovChain.plates

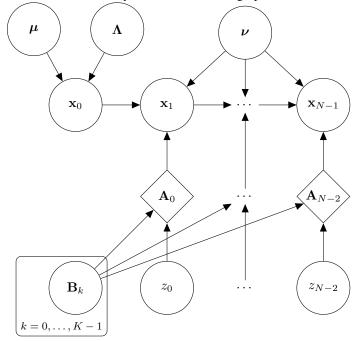

GaussianMarkovChain.plates = None

bayespy.nodes.SwitchingGaussianMarkovChain

class bayespy.nodes.SwitchingGaussianMarkovChain (mu, Lambda, B, Z, nu, n=None, **kwargs)

Node for Gaussian Markov chain random variables with switching dynamics.

The node models a sequence of Gaussian variables :math: $\{x\}_0$, idots, mathbf $\{x\}_{\{N-1\}}$ with linear Markovian dynamics. The dynamics may change in time, which is obtained by having a set of matrices and at each time selecting one of them as the state dynamics matrix. The graphical model can be presented as:

where μ and Λ are the mean and the precision matrix of the initial state, ν is the precision of the innovation noise, and \mathbf{A}_n are the state dynamics matrix obtained by selecting one of the matrices $\{\mathbf{B}_k\}_{k=0}^{K-1}$ at each time. The selections are provided by $z_n \in \{0, \dots, K-1\}$. The probability distribution is

$$p(\mathbf{x}_0, \dots, \mathbf{x}_{N-1}) = p(\mathbf{x}_0) \prod_{n=1}^{N-1} p(\mathbf{x}_n | \mathbf{x}_{n-1})$$

where

$$\begin{split} p(\mathbf{x}_0) &= \mathcal{N}(\mathbf{x}_0 | \boldsymbol{\mu}, \boldsymbol{\Lambda}) \\ p(\mathbf{x}_n | \mathbf{x}_{n-1}) &= \mathcal{N}(\mathbf{x}_n | \mathbf{A}_{n-1} \mathbf{x}_{n-1}, \operatorname{diag}(\boldsymbol{\nu})), \quad \text{for } n = 1, \dots, N-1, \\ \mathbf{A}_n &= \mathbf{B}_{z_n}, \quad \text{for } n = 0, \dots, N-2. \end{split}$$

Parameters mu : Gaussian-like node or (...,D)-array

 μ , mean of x_0 , D-dimensional with plates (...)

Lambda: Wishart-like node or (...,D,D)-array

 Λ , precision matrix of x_0 , $D \times D$ -dimensional with plates (...)

B: Gaussian-like node or (...,D,D,K)-array

 $\{\mathbf{B}_k\}_{k=0}^{K-1}$, a set of state dynamics matrix, $D \times K$ -dimensional with plates (...,D)

Z: categorical-like node or (...,N-1)-array

 $\{z_0, \ldots, z_{N-2}\}$, time-dependent selection, K-categorical with plates (...,N-1)

nu: gamma-like node or (...,D)-array

 ν , diagonal elements of the precision of the innovation process, plates (...,D)

n: int, optional

N, the length of the chain. Must be given if \mathbf{Z} does not have plates over the time domain (which would not make sense).

See also:

```
Gaussian, GaussianARD, Wishart, Gamma, GaussianMarkovChain, VaryingGaussianMarkovChain, Categorical, CategoricalMarkovChain
```

Notes

Equivalent model block can be constructed with GaussianMarkovChain by explicitly using Gate to select the state dynamics matrix. However, that approach is not very efficient for large datasets because it does not utilize the structure of \mathbf{A}_n , thus it explicitly computes huge moment arrays.

bayespy.nodes.VaryingGaussianMarkovChain

class bayespy.nodes.VaryingGaussianMarkovChain (mu, Lambda, B, S, nu, n=None, **kwargs)
Node for Gaussian Markov chain random variables with time-varying dynamics.

The node models a sequence of Gaussian variables :math: $\{x\}_0$, in the factor of Gaussian variables :math: $\{x\}_0$, in t

where μ and Λ are the mean and the precision matrix of the initial state, ν is the precision of the innovation noise, and A_n are the state dynamics matrix obtained by mixing matrices B_k with weights $s_{n,k}$.

The probability distribution is

$$p(\mathbf{x}_0,\ldots,\mathbf{x}_{N-1}) = p(\mathbf{x}_0) \prod_{n=1}^{N-1} p(\mathbf{x}_n|\mathbf{x}_{n-1})$$

where

$$p(\mathbf{x}_0) = \mathcal{N}(\mathbf{x}_0 | \boldsymbol{\mu}, \boldsymbol{\Lambda})$$

$$p(\mathbf{x}_n | \mathbf{x}_{n-1}) = \mathcal{N}(\mathbf{x}_n | \mathbf{A}_{n-1} \mathbf{x}_{n-1}, \operatorname{diag}(\boldsymbol{\nu})), \quad \text{for } n = 1, \dots, N-1,$$

$$\mathbf{A}_n = \sum_{k=0}^{K-1} s_{n,k} \mathbf{B}_k, \quad \text{for } n = 0, \dots, N-2.$$

Parameters mu: Gaussian-like node or (...,D)-array

 μ , mean of x_0 , D-dimensional with plates (...)

Lambda: Wishart-like node or (...,D,D)-array

 Λ , precision matrix of x_0 , $D \times D$ -dimensional with plates (...)

B: Gaussian-like node or (...,D,D,K)-array

 $\{\mathbf{B}_k\}_{k=0}^{K-1}$, a set of state dynamics matrix, $D \times K$ -dimensional with plates (...,D)

S: Gaussian-like node or (...,N-1,K)-array

 $\{s_0, \dots, s_{N-2}\}$, time-varying weights of the linear combination, K-dimensional with plates (...,N-1)

nu: gamma-like node or (...,D)-array

 ν , diagonal elements of the precision of the innovation process, plates (...,D)

n: int, optional

N, the length of the chain. Must be given if **S** does not have plates over the time domain (which would not make sense).

Gaussian, GaussianARD, Wishart, Gamma, GaussianMarkovChain, SwitchingGaussianMarkovChain
```

Notes

Equivalent model block can be constructed with GaussianMarkovChain by explicitly using SumMultiply to compute the linear combination. However, that approach is not very efficient for large datasets because it does not utilize the structure of \mathbf{A}_n , thus it explicitly computes huge moment arrays.

5.1. Nodes 115

Load the state of the node from a HDF5 file.

bayespy.nodes.VaryingGaussianMarkovChain.logpdf

VaryingGaussianMarkovChain.logpdf (*X*, *mask=True*)

Compute the log probability density function Q(X) of this node.

bayespy.nodes.VaryingGaussianMarkovChain.lower bound contribution

VaryingGaussianMarkovChain.lower_bound_contribution(gradient=False)

bayespy.nodes.VaryingGaussianMarkovChain.lowerbound

VaryingGaussianMarkovChain.lowerbound()

bayespy.nodes.VaryingGaussianMarkovChain.move_plates

VaryingGaussianMarkovChain.move_plates(from_plate, to_plate)

bayespy.nodes.VaryingGaussianMarkovChain.observe

VaryingGaussianMarkovChain.**observe**(*x*, **args*, *mask=True*) Fix moments, compute f and propagate mask.

bayespy.nodes.VaryingGaussianMarkovChain.pdf

VaryingGaussianMarkovChain.pdf (*X*, *mask=True*)
Compute the probability density function of this node.

bayespy.nodes.VaryingGaussianMarkovChain.plot

VaryingGaussianMarkovChain.plot(**kwargs)

Plot the node distribution using the plotter of the node

Because the distributions are in general very difficult to plot, the user must specify some functions which performs the plotting as wanted. See, for instance, bayespy.plot.plotting for available plotters, that is, functions that perform plotting for a node.

bayes py. nodes. Varying Gaussian Markov Chain. random

VaryingGaussianMarkovChain.random()

Draw a random sample from the distribution.

bayespy.nodes.VaryingGaussianMarkovChain.rotate

VaryingGaussianMarkovChain.rotate(R, inv=None, logdet=None)

bayespy.nodes.VaryingGaussianMarkovChain.save

VaryingGaussianMarkovChain.save (group)
Save the state of the node into a HDF5 file.
group can be the root

bayespy.nodes.VaryingGaussianMarkovChain.set_plotter

VaryingGaussianMarkovChain.set_plotter(plotter)

bayespy.nodes.VaryingGaussianMarkovChain.show

VaryingGaussianMarkovChain.show()

bayespy.nodes.VaryingGaussianMarkovChain.unobserve

VaryingGaussianMarkovChain.unobserve()

bayespy.nodes.VaryingGaussianMarkovChain.update

VaryingGaussianMarkovChain.update()

Attributes

dims plates

bayespy.nodes.VaryingGaussianMarkovChain.dims

VaryingGaussianMarkovChain.dims = None

bayes py. nodes. Varying Gaussian Markov Chain. plates

VaryingGaussianMarkovChain.plates = None

Other stochastic nodes:

Mixture(z, node class, *params[, cluster plate]) Node for exponential family mixture variables.

bayespy.nodes.Mixture

class bayespy.nodes.**Mixture** (*z*, *node_class*, **params*, *cluster_plate=-1*, ***kwargs*) Node for exponential family mixture variables.

The node represents a random variable which is sampled from a mixture distribution. It is possible to mix any

exponential family distribution. The probability density function is

$$p(x|z=k, \boldsymbol{\theta}_0, \dots, \boldsymbol{\theta}_{K-1}) = \phi(x|\boldsymbol{\theta}_k),$$

where ϕ is the probability density function of the mixed exponential family distribution and $\theta_0, \dots, \theta_{K-1}$ are the parameters of each cluster. For instance, ϕ could be the Gaussian probability density function $\mathcal N$ and $\theta_k = \{\mu_k, \Lambda_k\}$ where μ_k and Λ_k are the mean vector and precision matrix for cluster k.

Parameters z: categorical-like node or array

z, cluster assignment

node_class: stochastic exponential family node class

Mixed distribution

params: types specified by the mixed distribution

Parameters of the mixed distribution. If some parameters should vary between clusters, those parameters' plate axis *cluster_plate* should have a size which equals the number of clusters. For parameters with shared values, that plate axis should have length 1. At least one parameter should vary between clusters.

cluster_plate: int, optional

Negative integer defining which plate axis is used for the clusters in the parameters. That plate axis is ignored from the parameters when considering the plates for this node. By default, mix over the last plate axis.

See also:

Categorical, CategoricalMarkovChain

Examples

A simple 2-dimensional Gaussian mixture model with three clusters for 100 samples can be constructed, for instance, as:

Methods

```
add_plate_axis(to_plate)

delete() Delete this node and the children

get_mask()

get_moments()

get_shape(ind)

has_plotter() Return True if the node has a plotter

initialize_from_parameters(*args)

initialize_from_prior()

initialize_from_random() Set the variable to a random sample from the current distribution.
```

Approximates the posterior predictive pdf int p(x|parents) q(parents) dparent

Compute the log probability density function Q(X) of this node.

Load the state of the node from a HDF5 file.

```
move_plates(from_plate, to_plate)
observe(x, *args[, mask])
                                                  Fix moments, compute f and propagate mask.
pdf(X[, mask])
                                                  Compute the probability density function of this node.
plot(**kwargs)
                                                  Plot the node distribution using the plotter of the node
random()
                                                  Draw a random sample from the distribution.
save(group)
                                                  Save the state of the node into a HDF5 file.

```

5.1.2 Deterministic nodes

Dot(*args, **kwargs)	Node for computing inner product of several Gaussian vectors.
<pre>SumMultiply(*args[, iterator_axis])</pre>	Node for computing general products and sums of Gaussian nodes.
<pre>Gate(Z, X[, gated_plate, moments])</pre>	Deterministic gating of one node.

bayespy.nodes.Dot

```
bayespy.nodes.Dot(*args, **kwargs)
```

Node for computing inner product of several Gaussian vectors.

This is a simple wrapper of the much more general SumMultiply. For now, it is here for backward compatibility.

bayespy.nodes.SumMultiply

```
class bayespy.nodes.SumMultiply(*args, iterator_axis=None, **kwargs)
```

Node for computing general products and sums of Gaussian nodes.

The node is similar to *numpy.einsum*, which is a very general function for computing dot products, sums, products and other sums of products of arrays.

For instance, the equivalent of

```
np.einsum('abc,bd,ca->da', X, Y, Z)
would be given as
SumMultiply('abc,bd,ca->da', X, Y, Z)
or
SumMultiply(X, [0,1,2], Y, [1,3], Z, [2,0], [3,0])
```

which is similar to the other syntax of numpy.einsum.

This node operates similarly as numpy.einsum. However, you must use all the elements of each node, that is, an operation like np.einsum('ii->i',X) is not allowed. Thus, for each node, each axis must be given unique id. The id identifies which axes correspond to which axes between the different nodes. Also, Ellipsis ('...') is not yet supported for simplicity. It would also have some problems with constant inputs (because how to determine ndim), so let us just forget it for now.

Each output axis must appear in the input mappings.

The keys must refer to variable dimension axes only, not plate axes.

The input nodes may be Gaussian-gamma (isotropic) nodes.

The output message is Gaussian-gamma (isotropic) if any of the input nodes is Gaussian-gamma.

Notes

This operation can be extremely slow if not used wisely. For large and complex operations, it is sometimes more efficient to split the operation into multiple nodes. For instance, the example above could probably be computed faster by

```
XZ = SumMultiply(X, [0,1,2], Z, [2,0], [0,1])

F = SumMultiply(XZ, [0,1], Y, [1,2], [2,0])
```

because the third axis ('c') could be summed out already in the first operation. This same effect applies also to numpy.einsum in general.

Examples

Sum over the rows: 'ij->j'

Inner product of three vectors: 'i,i,i'

Matrix-vector product: 'ij,j->i'

Matrix-matrix product: 'ik,kj->ij'

Outer product: 'i,j->ij'

Vector-matrix-vector product: 'i,ij,j'

Methods

bayespy.nodes.SumMultiply.add_plate_axis

```
SumMultiply.add_plate_axis(to_plate)
```

bayespy.nodes.SumMultiply.delete

```
SumMultiply.delete()

Delete this node and the children
```

bayespy.nodes.SumMultiply.get_mask

```
SumMultiply.get_mask()
```

```
bayespy.nodes.SumMultiply.get_moments
SumMultiply.get_moments()
bayespy.nodes.SumMultiply.get_parameters
SumMultiply.get_parameters()
bayespy.nodes.SumMultiply.get_shape
SumMultiply.get_shape(ind)
bayespy.nodes.SumMultiply.has_plotter
SumMultiply.has_plotter()
    Return True if the node has a plotter
bayespy.nodes.SumMultiply.lower bound contribution
SumMultiply.lower_bound_contribution(gradient=False)
bayespy.nodes.SumMultiply.move_plates
SumMultiply.move_plates (from_plate, to_plate)
bayespy.nodes.SumMultiply.plot
SumMultiply.plot(**kwargs)
    Plot the node distribution using the plotter of the node
    Because the distributions are in general very difficult to plot, the user must specify some functions which
    performs the plotting as wanted. See, for instance, bayespy.plot.plotting for available plotters, that is,
    functions that perform plotting for a node.
bayespy.nodes.SumMultiply.set_plotter
SumMultiply.set_plotter(plotter)
Attributes
                         plates
bayespy.nodes.SumMultiply.plates
SumMultiply.plates = None
```

bayespy.nodes.Gate

```
class bayespy.nodes.Gate(Z, X, gated_plate=-1, moments=None, **kwargs)
    Deterministic gating of one node.
```

Gating is performed over one plate axis.

Note: You should not use gating for several variables which parents of a same node if the gates use the same gate assignments. In such case, the results will be wrong. The reason is a general one: A stochastic node may not be a parent of another node via several paths unless at most one path has no other stochastic nodes between them.

Methods

bayespy.nodes.Gate.add_plate_axis

```
bayespy.nodes.Gate.delete

Gate.delete()
    Delete this node and the children

bayespy.nodes.Gate.get_mask

Gate.get_mask()
```

bayespy.nodes.Gate.get_moments

Gate.get_moments()

bayespy.nodes.Gate.get_shape

Gate.get_shape(ind)

bayespy.nodes.Gate.has plotter

```
Gate.has_plotter()
```

Return True if the node has a plotter

bayespy.nodes.Gate.lower bound contribution

Gate.lower_bound_contribution (gradient=False)

bayespy.nodes.Gate.move_plates

Gate.move_plates (from_plate, to_plate)

bayespy.nodes.Gate.plot

```
Gate.plot (**kwargs)
```

Plot the node distribution using the plotter of the node

Because the distributions are in general very difficult to plot, the user must specify some functions which performs the plotting as wanted. See, for instance, bayespy.plot.plotting for available plotters, that is, functions that perform plotting for a node.

bayespy.nodes.Gate.set_plotter

Gate.set_plotter(plotter)

Attributes

plates

bayespy.nodes.Gate.plates

Gate.plates = None

5.1.3 Base nodes (for developers)

These nodes should be interesting only for developers.

node.Node(*parents, **kwargs)	Base class for all nodes.
stochastic.Stochastic(*args[, initialize, dims])	Base class for nodes that are stochastic.
<pre>deterministic.Deterministic(*args, **kwargs)</pre>	Base class for deterministic nodes.

bayespy.inference.vmp.nodes.node.Node

```
class bayespy.inference.vmp.nodes.node.Node(*parents, **kwargs)
    Base class for all nodes.
```

mask dims plates parents children name

Sub-classes must implement: 1. For computing the message to children:

```
get_moments(self):
```

2.For computing the message to parents: _get_message_and_mask_to_parent(self, index)

Sub-classes may need to re-implement: 1. If they manipulate plates:

```
_compute_mask_to_parent(index, mask) _plates_to_parent(self, index) _plates_from_parent(self, index)
```

Methods

```
add_plate_axis(to_plate)
delete() Delete this node and the children
get_mask()
get_moments()
get_shape(ind)
has_plotter() Return True if the node has a plotter
move_plates(from_plate, to_plate)
plot(**kwargs) Plot the node distribution using the plotter of the node
set_plotter(plotter)
```

bayespy.inference.vmp.nodes.node.Node.add_plate_axis

```
Node.add_plate_axis(to_plate)
```

bayespy.inference.vmp.nodes.node.Node.delete

```
Node.delete()
```

Delete this node and the children

$bayespy. inference. vmp. nodes. node. Node. get_mask$

Stochastic.save(group)
```

Save the state of the node into a HDF5 file.

group can be the root

$bayes py. inference. vmp. nodes. stochastic. Stochastic. set_plotter$

```
Stochastic.set_plotter(plotter)
```

bayespy.inference.vmp.nodes.stochastic.Stochastic.unobserve

```
Stochastic.unobserve()
```

bayespy.inference.vmp.nodes.stochastic.Stochastic.update

```
Stochastic.update()
```

Attributes

plates

bayespy.inference.vmp.nodes.stochastic.Stochastic.plates

Stochastic.plates = None

bayespy.inference.vmp.nodes.deterministic.Deterministic

Sub-classes must implement: 1. For implementing the deterministic function:

```
_compute_moments(self, *u)
```

2.One of the following options: a) Simple methods:

```
_compute_message_to_parent(self, index, m, *u) not? _compute_mask_to_parent(self, index, mask)
```

(a)More control with: _compute_message_and_mask_to_parent(self, index, m, *u)

Sub-classes may need to re-implement: 1. If they manipulate plates:

```
_compute_mask_to_parent(index, mask) _plates_to_parent(self, index) _plates_from_parent(self, index)
```

Methods

```
add_plate_axis(to_plate)
delete() Delete this node and the children
get_mask()
get_moments()
get_shape(ind)
has_plotter() Return True if the node has a plotter
lower_bound_contribution([gradient])
move_plates(from_plate, to_plate)
plot(**kwargs) Plot the node distribution using the plotter of the node
set_plotter(plotter)
```

$bayes py. inference. vmp. nodes. deterministic. Deterministic. add_plate_axis$

```
Deterministic.add_plate_axis(to_plate)
```

bayespy.inference.vmp.nodes.deterministic.Deterministic.delete

```
Deterministic.delete()

Delete this node and the children
```

```
bayespy.inference.vmp.nodes.deterministic.Deterministic.get_mask
Deterministic.get_mask()
bayespy.inference.vmp.nodes.deterministic.Deterministic.get moments
Deterministic.get_moments()
bayespy.inference.vmp.nodes.deterministic.Deterministic.get_shape
Deterministic.get_shape (ind)
bayespy.inference.vmp.nodes.deterministic.Deterministic.has_plotter
Deterministic.has_plotter()
    Return True if the node has a plotter
bayespy.inference.vmp.nodes.deterministic.Deterministic.lower bound contribution
Deterministic.lower bound contribution (gradient=False)
bayespy.inference.vmp.nodes.deterministic.Deterministic.move_plates
Deterministic.move_plates (from_plate, to_plate)
bayespy.inference.vmp.nodes.deterministic.Deterministic.plot
Deterministic.plot(**kwargs)
    Plot the node distribution using the plotter of the node
    Because the distributions are in general very difficult to plot, the user must specify some functions which
    performs the plotting as wanted. See, for instance, bayespy.plot.plotting for available plotters, that is,
    functions that perform plotting for a node.
bayespy.inference.vmp.nodes.deterministic.Deterministic.set_plotter
Deterministic.set_plotter(plotter)
Attributes
                         plates
bayespy.inference.vmp.nodes.deterministic.Deterministic.plates
```

Deterministic.plates = None

constant.Constant(moments, x, **kwargs) Node for presenting constant values.

bayespy.inference.vmp.nodes.constant.Constant

class bayespy.inference.vmp.nodes.constant.Constant(moments, x, **kwargs)
 Node for presenting constant values.

The node wraps arrays into proper node type.

Methods

bayespy.inference.vmp.nodes.constant.Constant.add plate axis

```
Constant.add_plate_axis(to_plate)
```

bayes py. inference. vmp. nodes. constant. Constant. delete

```
Constant.delete()

Delete this node and the children
```

bayespy.inference.vmp.nodes.constant.Constant.get_mask

```
Constant.get_mask()
```

bayespy.inference.vmp.nodes.constant.Constant.get moments

```
Constant.get moments()
```

$bayes py. inference. vmp. nodes. constant. Constant. get_shape$

```
Constant.get_shape (ind)
```

bayespy.inference.vmp.nodes.constant.Constant.has_plotter

```
Constant.has_plotter()

Return True if the node has a plotter
```

bayespy.inference.vmp.nodes.constant.Constant.move_plates

Constant.move_plates (from_plate, to_plate)

bayespy.inference.vmp.nodes.constant.Constant.plot

```
Constant.plot(**kwargs)
```

Plot the node distribution using the plotter of the node

Because the distributions are in general very difficult to plot, the user must specify some functions which performs the plotting as wanted. See, for instance, bayespy.plot.plotting for available plotters, that is, functions that perform plotting for a node.

bayespy.inference.vmp.nodes.constant.Constant.set_plotter

Constant.set_plotter(plotter)
